But, valuable as are notes and abstracts in assisting to fix permanently facts difficult of remembrance, they are not to be compared with drawings and diagrams in this respect. If a student can make a correct drawing of a dissection or of a pathological condition, it is an objective demonstration that he knows it; and a good drawing, occupying but a few inches of his manuscript, tells often more than pages of verbose explanation. In pathology particularly, the relations of organs to neighbouring parts are often so disturbed, and the appearances they present so irregular, that they almost defy description in words, whilst many of them lend themselves with peculiar aptness to pictorial illustration. An objection which the beginner at once puts forward is, "But I have no idea of drawing." Yet no one will be more surprised than he himself at the rapid progress he can make in this direction if he takes the pains to begin making diagrams, and his surprise will be the greater when there dawn upon him the multitudinous uses to which this diagram method can be put, for it can be made to delineate not only outlines of objects, but also skeletons of theories. It encourages, too, the development of a most valuable faculty, that of observation—a faculty which students, as a rule, are averse to commence to cultivate, because they find that it requires much pains, while the immediate benefit is not apparent to them. And from the first it is important to make single precise observations. The determination of the density of a tumour should be accomplished by a single well-directed act of manipulation, and multiple aimless examinations should be avoided. The same holds good with inspection, percussion, and auscultation. Let each individual act of examination be done with a purpose; the patient will then be spared much discomfort, and the investigator will have gained all the knowledge he seeks.

Throughout his ward training the student will find that the practical application of these principles will bring him the best results for his labour. It is quite impossible to over-estimate the value of confirming at every opportunity the truth of clinical facts. Here, again, in investigating the nature of a malady at the bedside, one should have a method, and should follow it closely. In every instance, unless there is some special reason for exception, the "instructions for case-taking" should be adhered to, for many collateral facts likely otherwise to be overlooked are thus brought to light. The questioning should not be confined to the patient, but any point not clear to the mind of the investigator should form the subject of an interpellation of the teacher. Get into the habit of asking questions. Many men from shyness walk away from a bed with an entirely wrong idea as to the illness or its treatment, when one or two simple queries would have cleared up the whole matter. Others, again, men perhaps old in years but young in knowledge, appear to evade the asking of questions for fear of discovering to others their want of familiarity with the subject. This is the worst form of pride, and is fatal to the acquisition of useful information. It is wonderful how the art of questioning improves

Digitized by Google

with practice. Follow a distinguished physician or surgeon in his round through the wards, and surprise will be over and over again evoked at the rapidity with which he not only lays bare the whole history of a malady, but connects it with antecedents of inheritance, of climate, of occupation. He, too, will often show how events in a life-history of apparently no moment are really landmarks of important clinical significance.

As the asking of questions is valuable as a means of gaining knowledge, so is it most needful to study the art of answering them. The importance of this is clearly recognised by the examining bodies, who require not only evidence of attendance on lectures, but also of attaining to a certain standard of proficiency in the periodical examinations held in connexion with each class. The educational value of these is very great, for to the steady worker they serve as a means of discovering whether in the ground covered by the course of instruction the facts have become fixed, and they give the student opportunities of committing statements to paper in the form required in the more important examinations later on. They should therefore be diligently attended, and if the results attained indicate a weakness in this direction, it can be corrected without the annoyance and expense of a rejection by a public examining body.

Sufficient has probably been said with regard to the general work of the student to indicate the lines that should be pursued; but it remains to anticipate his experience by pointing out that, though some of the practical work will at first be disagreeable, much of it will call forth sensations of real pleasure. Practical microscopy, for instance, has now almost reached the position of a fine art, and, apart from the value of the acquisition of gentleness of touch which must be learnt in attending a course, the results of the work itself are beautiful. The art of staining has almost reached perfection, and tissues which formerly, being imperfectly coloured, appeared difficult of recognition, now cannot fail to arrest the attention when clothed in the glorious tints of a double or triple dye. The whole field of bacteriology, too, is now open, and the study is being followed with enthusiasm by many in what little leisure they can afford, and they care as tenderly for their crops of cultivations as the orchid grower does for his larger parasites.

Throughout the whole period of study the health should be attended to, and physical recreation should, equally with work, have its share of the day allotted. Many men keep a dog, which not only serves as a faithful companion, but to give it proper exercise a walk of at least a couple of miles a day must be undertaken by its master. For the organisation of sports there are attached to every hospital athletic clubs, and we note with pleasure that at two or three at least of them the clubs have been amalgamated; the advantages of this are obvious, for it not only tends to economy but ensures a community of interest.

Finally, let those preparing for the profession never forget the importance of developing the social side of their existence. Students, if left to themselves, are apt to fall into one of two grades. On the one hand, those who, almost continually at study, allow themselves no time for relaxation, but live their lives for the time being in and for their work. Their ideas become narrow, their countenances sombre, their complexion sallow, their gait stooping; they are absent-minded, and seem often offended at the trivialities of a joke. They become labelled "smugs," and are avoided by their class-mates, which renders their position even more isolated than before. Continuing their lonely course, they pass, usually with ease, their final examinations, and then find themselves face to face with a world they have for four years affected to ignore. Such men are embarrassed in the presence of their patients, and show obvious discomfort when endeavouring to participate in the pleasures of the social circle. The world, like their school, speedily tires of them; their patients, preferring a cheerful face and easy manner in their medical adviser, desert them, and their home becomes a hermitage. On the other hand, those are to be met with who, responding to the craving for a companionship not to be found in the sober temples of science, and dissatisfied with the monotony of mental labour—freed also, perhaps, but recently from the restraints of a school or the ties of a home circle,—plunge headlong into a whirlpool of gaiety, and time, passing unheeded, brings them all too soon to the end of their curriculum. And then follows the awakening; for even supposing they have been able, by the aid of skilled "coaches" and the forced marches of pernicious cramming, to reach the goal of qualification, they find themselves approaching the investigation of cases with nervous apprehension, and their life becomes one long round of regret at opportunities lost; they are ever impressed with a keen sense of their own incapacity, and ever fearful lest this private impression should become public knowledge. We have purposely sketched the extremes of each type; and our object is, not to intemperately recommend that neither should be followed in any point, but to insist on the truth of the old maxim, *in medio tutissimus ibis*—that the truly happy life is that which combines work and recreation in their proper proportions; that the model medical man is he who, possessing knowledge of the theory and skill in the practice of his profession, combines with these the attributes of a gentleman. For this very purpose, to encourage work and to give with it the advantages of cheerful companionship, collegiate life is to be strongly recommended. At a few of the medical schools residential colleges have been either some time existent or have been recently erected, and they open their doors not only to those who, having received at the older universities a preliminary training in arts and science, are desirous of entering upon practical clinical work in a wider field, but also to that larger number who come straight from school to begin their medical studies. Those who have at heart the moral welfare of their wards are not slow to avail themselves of the advantages offered by these institutions, where students can work under the guidance of a warden, and under comfortable conditions of life, in close association with men of their own standing. Thus, judiciously controlled, but not placed under vexatious restrictions, they avoid altogether the lonely lodging with its attendant temptations.

We who have chosen the profession of medicine have had handed down to us traditions of which we are most justly proud, and many who have gone before us have set noble examples of self-denying heroism and of unselfish courage. Upon our shoulders lies the burden of safeguarding the health of the community; to each of us may many times be

Digitized by Google

entrusted the lives of breadwinners—may more than once be confided the secrets of a life; it behoves us, therefore, so to train ourselves that we may be capable of bearing these burdens, that we may prove worthy of the confidence reposed in us. The responsibility commences with the first hour of our lives as students, and, increasing as we go on, ceases not till the race is run. Let the knowledge of this responsibility stimulate us ever to the acquisition of fresh facts; let each endeavour to add his jot or tittle to the mass of information which, placed at our disposal by the labours of our predecessors and contemporaries, and applied by us in the practice of our art, may serve to alleviate human suffering. Then indeed, in our later years, contemplation of the time spent in the practice of a vocation dedicated to such noble objects can but be a pleasant retrospect, carrying with it the conviction that life's journey has not been undertaken in vain.

DEGREES FOR LONDON MEDICAL STUDENTS.

DURING the past twelve months the movement for granting degrees to the medical students educated in London, on conditions of examination similar to those on which they are awarded in the Scottish and Provincial Universities, has made an important step forwards. The Report of the Royal Commission appointed to inquire into the question has been issued, and its recommendations are entirely in accord with the proposals of the advocates of the movement. The Commissioners say that they are satisfied "that a great demand exists for medical degrees attainable in London more easily than at present, and that it may be desirable to provide for that want in some proper manner." This legitimate grievance of London medical students, on which THE LANCET has for so long insisted, is thus fully recognised; but, being admitted, a difficulty arises as to the best means for its removal. The Commissioners unanimously conclude that the granting of the degrees by "such a body as the Senate of Physicians and Surgeons proposed by the Royal Colleges would not be the best means by which that end could be attained," and hence the remedy must be found either in so changing the character of the existing University of London as to adapt it to this purpose, or in founding a new University. University and King's Colleges had presented a petition to the Privy Council, and the heads of those Colleges, who were heard before the Commission in favour of the latter alternative, urged that they were Colleges of great academic weight and character, and of sufficient standing to become the nucleus of a new degree-giving and examining University in all faculties. Of the constitution of the Medical Faculty, the medical schools separately, or as represented by the Royal Colleges of Physicians and Surgeons, were to form an integral part. If this scheme had been adopted, the University of London would have remained as at present an imperial examining board. The members of the Royal Commission were all agreed in the opinion that the general case for a real Teaching University in London is made out; but, unfortunately for the settling of the question, they were not similarly unanimous as to whether the establishment of this Teaching University should be brought about by the extension of the present University or by the creation of a new University, as proposed by University and King's Colleges. The practical educationists on the Commission—Sir WILLIAM THOMSON, Sir G. G. STOKES, and Mr. WELLDON—preferred "the establishment of a new Teaching University for London, leaving it to the London University to continue to discharge its present functions." The legal members of the Commission—Lord SELBORNE, Vice-Chancellor BALL, and Sir JAMES HANNEN, —however, attached more importance to the inconvenience of having two distinct Universities in London discharging totally different functions, and were therefore in favour of so altering the constitution of the existing institution as to unite the teaching and examining functions in a single University. With this object in view, they recommended the Senate and Convocation of the University of London to apply for a new Charter, "extending its functions and duties to teaching; associating with it teaching colleges and institutions; remodelling the constitution of its Senate; establishing as electoral bodies the teachers of its constituent and associated colleges and institutions in the several faculties of Arts, Science, Laws, and Medicine; establishing boards of studies, and otherwise granting new powers to the University"; and to this recommendation the other members of the Commission have consented, and "a reasonable time" has been given to the authorities of the University of London to consider and take action upon the suggestions laid down in a detailed scheme for its reorganisation by the Commissioners in their report. The Lord President of the Privy Council has told a deputation that he considers a year a "reasonable time," and this will expire on April 29th, 1890. As to the present examination standard of the University, it is significantly noted that, "as to medical degrees, we think that a standard of attainment appropriate for honours ought no longer to be required by the University for an ordinary or 'pass' degree," and a paragraph (33) is devoted to showing how this alteration in the standard can be effected. Considerable changes have been made during the past year in the examinations in the strictly medical subjects, and further alterations in the scientific curriculum are announced for next year; but although these will increase the facilities for obtaining medical degrees, they do not, to any great extent, affect the standard, and it is in this respect that the chief difficulty of the University in meeting the views of the Commissioners lies. A real lowering of the "pass" standard to that of other Universities will alone satisfy the just wants of the average medical student in London, but such a lowering of the present exceptionally high standard would completely alter the value of its degrees, and be opposed to the views of most of its graduates. The Senate is now engaged in working out a scheme on the lines suggested by the Royal Commissioners, and this must be presented to Convocation during the coming winter session. Until this has been done, and Convocation has decided on its acceptance or refusal, no further action can be taken by any of the bodies interested in the movement; but as the "period of grace" will expire before May next, it is to be hoped that a fair and suitable plan for giving the London student the advantages with respect to obtaining a degree which his fellow-students elsewhere now enjoy will be forthcoming, and be even advancing towards a satisfactory issue, before the commencement of the winter session of 1890.

CHANGES IN THE MEDICAL EXAMINATIONS.

THE chief alterations in the Examinations of the various Licensing Boards during the past year have been made by the Senate of the University of London with a view to increase the facilities for obtaining degrees at the University without lowering the existing standard; and experience, so far, has shown that these alterations have been to the advantage of the candidates. At the Final M.B. Examination in May candidates obtained degrees who in previous years would have had to wait until November next; and at the recent Intermediate M.B. Examination a far larger number of students than usual passed in the first division. The changes in the regulations for the M.D. Degree have not yet come into force, but they are sure to lead to an increase in the number of graduates as soon as the conditions are fully known; and the contemplated division of the Preliminary Scientific M.B. Examination into two distinct parts must increase the number of those who pass, by lessening the difficulties of by far the most severe examination in the whole series.

The changes instituted and proposed are as follow:—At the Matriculation Examination Botany has been included as an optional subject. At the Preliminary Scientific M.B. Examination the syllabus in Biology and in Experimental Physics has been modified, and in 1890 a practical examination in the latter subject will be introduced. In July, 1890, and thenceforward, this examination will be divided into two sections: (1) Chemistry and Physics, and (2) General Biology. These may be taken separately or together, and candidates who take the two sections together will be credited with either section in which they may have passed, though they may have failed to pass in the other. At the Intermediate M.B. Examination the questions for Pass and Honours have been submitted to the candidate in the same paper, and a free choice has been given to him in selecting therefrom, so that he may answer one or more Honours questions with a view to Honours or to a mere Pass only; and thus there is now no restriction on his making a choice from a very extended range of questions. A revised syllabus in Organic Chemistry will take effect in July, 1890. A Final M.B. Examination for a "pass" only will be held on the first Monday in May, in addition to the usual examination in July. Candidates for the degrees of M.D. and M.S. now have the option of presenting a "Thesis," which, if approved, will exempt them from the greater part of the examination; and State Medicine has been introduced as an alternative branch to Medicine and Obstetric Medicine in the M.D. Examination. The following important alteration in the regulations has a more general bearing and should be widely known:—

"Registered medical practitioners of not less than three years' standing and twenty-five years of age, having passed the Matriculation and Preliminary Scientific Examinations, are now admissible to the subsequent examinations for Degrees in Medicine and Surgery without the intervals prescribed by the regulations, on producing certificates that they have gone through the required course of training *at any time* previously."

At the Conjoint Examining Board for England, all candidates are now required to present themselves in Anatomy and Physiology together, instead of having an option of taking them separately as heretofore, and if the candidate does not obtain a prescribed minimum in both subjects he will be referred in both, even if he has obtained the requisite number of marks for a "pass" in one of these subjects. Consequent on the introduction of Surgery into the final subjects at the Society of Apothecaries, the Final Examination at that Board has been subdivided into two distinct sections, which are held at different dates. The University of Aberdeen have under consideration certain changes which will effect a much-desired reform in the examination scheme. The examination in General Science will be placed at an earlier period of the course; one examination in Anatomy will replace the two now held in this subject; Surgery will take its proper place in the Final Examination; Pathology will form a new subdivision of the Final Examination; and in general a greater subdivision of the whole examination will be permitted.

DENTAL EDUCATION.

THE practice of the dental specialty presents many advantages to those who wish to follow some branch of the "healing art." Although now an overcrowded calling, yet, owing to the salutary action of the Dentists Act and the restrictions put upon non-qualified practitioners, the number of new additions to the Dental Register, as shown by statistics, does not approach the number yearly erased from death and other causes, and each year it has become a more desirable profession both from these limitations and the higher education of the men enrolled. That necessary qualification—a certain age—before anything like a large practice can be secured, appertaining to most branches of Surgery, does not at present apply to dental work, as the public generally have little objection to a young dentist. This may in part be due to the fact that the younger generation have had much greater facilities of special education than their fathers, owing to the good work of the members of the staff of the Dental Hospital and of the National Dental Hospital in London, and also of many provincial dental hospitals.

In the dental branch of the profession there are few arts and sciences which cannot be laid under contribution. Surgery Medicine, Chemistry, Mechanics (a very important part of dentist's work), and a multitude of others, might be cited. Though a profession of great antiquity, specimens of dental art being found in Egyptian mummies 2000 years old, it may yet be considered in its infancy. The rapid changes which have taken place in its practice during recent years, and to which there seems hardly a limit, mark it out as a good field for an energetic man. On the other hand, it is an exceedingly laborious profession, both mentally and physically, and the incidental expenses are large. The social status of "dentists" as a body has greatly improved since the passing of the Dentists Act, before which anyone could style himself "Dentist"; but the social status of the dentist himself depends upon his individuality. We strongly urge any of our readers intending to take up dental surgery, not to be content with the Licentiateship of Dental Surgery simply, but to add the L.R.C.P. and M.R.C.S. It entails only an extra two years' studentship, and the amount of practical knowledge of general surgery and medicine gained

Digitized by Google

would in after-life more than compensate for the extra time spent, to say nothing of the advantage of being a member of the medical family, and not merely a distant relative. It is not absolutely necessary for a medical student who wishes to practise dental surgery to take the L.D.S. diploma, but at the same time it is to his interest to do so; for to gain a fair knowledge of the subject he must attend the special department of a general hospital (few of which—in London only Guy's—attempt to deal with the subject thoroughly), or at a special dental hospital; and, having done this, a little extra trouble will enable him to be admitted to the examination at the Conjoint Board, without whose diploma few dental appointments are available. Without going into the requirements of the L.D.S. candidate pure and simple, the special regulations for those taking the L.R.C.P. and M.R.C.S. and the L.D.S. are: Lectures upon Dental Anatomy and Physiology, Human and Comparative, two courses; Dental Surgery, two courses; Dental Mechanics, two courses; Metallurgy, one course; Practice of Dental Surgery, two years; apprenticeship to a competent practitioner in the details of Mechanical Dentistry for a period of not less than three years. And we cannot do better than quote the words of the Dean of the Dental Hospital of London on the subject of how best the student should distribute his time.

"During the mechanical apprenticeship, eighteen months of which is recognised by the College of Surgeons when taken previous to the preliminary examination, the student can receive instruction from any registered medical practitioner, or any pharmaceutical chemist, or at a public hospital, or infirmary, or dispensary, in Chemistry, including Chemical Physics, Practical Chemistry, Pharmacy and Materia Medica; and after the preliminary examination has been passed, he should register as both a dental and medical student, and present himself for examination in these subjects, before entering a hospital (or, if he prefers it, he may take the two latter later in his career—viz., at the second examination); then enter simultaneously at a general and dental hospital. At the expiration of his first winter session at a general hospital let him pass in Elementary Anatomy and Physiology; at the end of his second winter let him take Anatomy and Physiology. At the expiration of two years he may present himself for the dental licence; he will during these two years have been attending simultaneously both the general and dental hospital. During the remainder of his time he should devote himself to Surgery, Medicine, and Midwifery &c., in which subjects he may be examined at the expiration of two years from the time of passing the second examination. It is felt that the recent changes brought about by the amalgamation of the two Colleges have greatly increased the difficulty of obtaining these higher qualifications; such is not really the case, the curriculum being really simplified. For the convenience of reference the mode of procedure is tabulated as concisely as possible for the dental student to obtain the three diplomas: 1. Preliminary examination. 2. Apprenticeship. 3. Registration as a dental and medical student, or this latter can be postponed until entry at hospital. 4. During apprenticeship receiving instruction as above in Chemistry, Materia Medica, and Pharmacy, and passing in them at the Examination Hall. 5. Enter simultaneously at a dental and general hospital. 6. Pass in Elementary Anatomy and Physiology at end of first winter session. 7. Pass in Anatomy and Physiology at end of second winter session. 8. Take Dental Licence at end of second year. 9. Devote remainder of time to Medicine, Surgery, and Midwifery &c. 10. Pass, at expiration of two years from second examination, the final test of the two Colleges."

The requirements of the Colleges of Surgeons of Edinburgh, Glasgow, and Ireland are very similar.

WEAK POINTS IN MEDICAL EDUCATION.

IT will be no unkind thing to medical students to give them a hint in our present number of certain weak points in the present system of medical education, to which attention is being directed in various quarters, and which otherwise they might find out at a later stage of life and in a more unpleasant way. The Bill which has just passed through Parliament providing for the notification of infectious fevers by the medical attendant will accentuate a very serious duty on the medical profession—that of early and accurately diagnosing such diseases. And it serves this good purpose, if no other, that it reminds us that in the present system of medical education there is scarcely any opportunity of seeing these diseases throughout their whole course. This is a very grave defect, and one which must be met by the Medical Council and the Examining Boards. Meantime every student should make his own opportunities of seeing such diseases. An epidemic of measles or scarlet fever or small-pox should be utilised. There are few large towns in which those diseases cannot be seen and studied with a little management. Not to see them and to know them and how to treat them, is to labour under the disability and discredit of being unacquainted with every-day work—an ignorance which under the new law will be apt to be rudely and publicly disclosed.

Psychology and Mental Disease is another branch of medical education which is very much neglected. In connexion with the schools there is but little provision for seeing mental disease and studying the history of cases and of the early stages of such cases. Yet the early recognition of significant symptoms is all-important. Here, again, there are ways and means open to the diligent student of acquiring instruction in such branches of practice, and he will be the wisest man who does not wait for the pressure of the examining authorities.

The enormous development of the several branches of medical education of late has tended to diminish the attention paid to Medico-legal questions, and to leave them more absolutely in the hands of experts. This is almost inevitable. But we have been lately again reminded of the fact that at any moment the medical practitioner may be face to face with the gravest crimes and criminals, and that on his acuteness and accuracy of observation life and death and the detection of crime may turn. We believe with the late Dr. GRAVES that refined questions of toxicology must always be beyond the capacity of a practitioner immersed in the anxieties and duties of general and consulting practice. But it is important that medical education should include a sound knowledge, as far as it goes, of toxicology. Not only so; apart from toxicology there is a great range of knowledge pertaining to public health and morals which deserves systematic study from the medical man. Specially this constitutes what is known as State Medicine, and special degrees of such knowledge have henceforth to be guaranteed in those who are candidates for appoint-

Digitized by Google

ments as medical officers of health. But it will not do for the medical practitioner of the future to be altogether at the mercy, in regard to such subjects, of the medical officer of health. Respect for his own dignity and usefulness, as well as for the interest of his patients, will incline him to give some attention to this great subject.

Among the most seriously weak points in medical education hitherto have been the subjects of Midwifery and Gynæcology. The great Scottish schools have—until very lately, at least—contented themselves with exacting an attendance on six cases of labour. True, they have made up for it by giving a six months' course of lectures. But midwifery and gynæcology are eminently subjects that cannot be taught by lectures, and must be taught by cases. This has been recognised by many students in schools where the requisite clinical instruction could not, in the very nature of things, be given, and they have gone to Ireland or the Continent to make up for the defect. It is probable that all the instruction needed could be got, and got well, at home, if teachers in larger towns once realised the demand for it. Be this as it may, let students remember that the day is not far distant—perhaps the night—when, in a lonely place, miles away from all help, they will find it an inexpressible advantage to be able to recognise presentations, to apply instruments, to meet hæmorrhages, and, in the more leisurely work of practice, to differentiate and deal with uterine and ovarian disease. Closely allied with this branch of medicine, and yet quite distinct from it, is the knowledge of Children's Diseases, which constitute so large a part of medical practice, but which are so little seen in the ordinary routine of hospital practice. The moral of all this is that students are to lose no opportunity anywhere of making their knowledge of disease more minute, especially of such diseases as are common. Rare cases are very interesting, but common diseases are of momentous consequence, and he will be the best and most successful practitioner who lays early a sound foundation in a knowledge of them, of their treatment, and of the treatment of those complications which tend most to the permanent injury of patients.

THE CHOICE OF A TEXT-BOOK.

THE selection of a text-book is a matter of great importance to the student, but the large number and variety of works of this class render the choice somewhat difficult. In the hope that it may be of some use as an indication of the course of reading best adapted for the curriculum, we reproduce (with certain additions) the advice given for some years past in these columns, arranging the works as a matter of convenience under the heads of the leading examining bodies in the metropolis—viz., the Examining Board for England (Royal College of Physicians and Royal College of Surgeons) and the University of London.

THE EXAMINING BOARD FOR ENGLAND.

For the *First* Examination of this Board the student will be required to have gained a fair knowledge of Elementary Anatomy and Physiology, of Chemistry, Materia Medica, and Pharmacy; and if he be diligent he should be able to pass both parts of the examination by the close of his first year. In *Anatomy*, he may have recourse to GRAY'S Text-book, and to the works on *Osteology* by WARD, HOLDEN, and NORTON. In *Physiology*, the Elementary Text-book of HUXLEY might well be mastered first. It will be enough for the first term of study. In *Chemistry*, ROSCOE'S Elementary book and ATTFIELD'S work. In *Chemical Physics*, FOWNES' Inorganic Chemistry edited by WATTS, or BALFOUR STEWART'S Elementary Physics. In *Materia Medica*, the works of MITCHELL BRUCE, WHITLA, ROBERTS, GARROD'S Essentials (edited by TIRARD), and BRUNTON'S or OWEN'S Elements.

For the *Second* Examination (corresponding to the Primary Membership at the College of Surgeons), the subject of *Anatomy* may be well studied in GRAY'S Anatomy, ELLIS'S Demonstrations, and HEATH'S Practical Anatomy. The anatomical plates of ELLIS and those of GODLEE, or the handier volume of MASSE, are very useful in supplementing practical work. In *Physiology*, the books most to be recommended are KIRKES' Handbook, G. YEO'S Text-book, H. POWER'S Elements, and MAPOTHER'S Manual: and *Histology*, apart from the sections devoted to it in the works of GRAY and KIRKES, may be studied in KLEIN'S Elements and SCHÄFER'S Essentials.

For the *Third* or Final Examination, in the subjects of *Surgery* and *Surgical Anatomy*, there are the Text-books of BRYANT, HOLMES, GANT, and ERICHSEN (edited by MARCUS BECK), the System of Surgery edited by TREVES, the Practical Manuals of BERKELEY HILL, CHRISTOPHER HEATH, PEARCE GOULD, and TREVES' Applied Surgical Anatomy. For *Surgical Pathology*, PEPPER, BOWLBY, or BILLROTH may be recommended. In *Diseases of the Eye*, LAWSON or NETTLESHIP. In *Medicine*, the Text-books of ROBERTS and BRISTOWE, preceded by the smaller works of CARTER or CHARTERIS. *Clinical Medicine:* FENWICK, FINLAYSON, or GRAHAM BROWN. GEE'S Auscultation and Percussion, and V. HARRIS'S Diseases of the Chest, are most valuable guides to physical diagnosis. *Pathology:* GREEN (edited by STANLEY BOYD), COATS, PAYNE, and ZIEGLER (MACALISTER'S translation), and WOODHEAD'S or STEVEN'S practical work. *Therapeutics:* BARTHOLOW, RINGER, NAPHEYS, and FARQUHARSON. *Medical Jurisprudence:* the Text-books of GUY and TAYLOR. *Public Health:* WILSON. *Midwifery:* PLAYFAIR or GALABIN, and HART and BARBOUR.

COLLEGE OF SURGEONS.

In addition to the anatomical and physiological works above mentioned, there may be read for the Primary F.R.C.S. (especially its histological and embryological sections)—QUAIN'S Anatomy, FOSTER'S Text-book of Physiology, LANDOIS' work edited by STIRLING, and GEGENBAUR'S Comparative Anatomy. Professor FLOWER'S Osteology of the Mammalia might also be read. For the Pass Examination, ERICHSEN'S work may be supplemented by chapters in the System of Surgery edited by HOLMES and HULKE. In *Operative and Practical Surgery*, there are works by STIMSON, FERGUSSON, and S. SMITH and HEATH'S Atlas. PAGET'S or BILLROTH'S Surgical Pathology and ZIEGLER'S Pathology may be profitably read in connexion with works mentioned under the Conjoint Examination.

UNIVERSITY OF LONDON EXAMINATIONS.

For the Intermediate M.B. Examination of the University of London, the subject of *Organic Chemistry* may be studied

Digitized by Google

in the Text-books of WILLIAMSON and of FOWNES. *Materia Medica*, besides the books above mentioned, is more fully treated in the works of BRUNTON, PHILLIPS, BARTHOLOW, and H. G. WOOD. *Physiology* as for the Primary F.R.C.S., with perhaps the addition of such books as that of POWER and HARRIS for practical work and of SCHÄFER for practical histology. The anatomical text-books are those recommended above. For the M.B. Examination, the subject of *Medicine* may profitably be further studied in NIEMEYER'S Text-book, in the exhaustive and scientific treatise of the late Dr. HILTON FAGGE, in that of AUSTIN FLINT, in the admirable work of STRUMPELL, in REYNOLDS' System of Medicine, and in TROUSSEAU'S Lectures. The large System of Medicine by American authors edited by Dr. WM. PEPPER contains articles which may often be usefully consulted by those who are desirous of obtaining full and accurate information. Special monographs (see M.D. Exam.) may also be consulted. *Pathology*, which should be worked at practically, may be studied in GREEN'S, COATS', PAYNE'S, ZIEGLER'S, or HAMILTON'S Text-books, and also in the work of WILKS and MOXON (of which a new edition has lately appeared), and in that of CORNIL and RANVIER; *Midwifery*, in the writings of PLAYFAIR, GALABIN, LEISHMAN, LUSK, and BARNES; *Gynæcology*, in those of GALABIN, LOMBE ATTHILL, EDIS, M. JONES, and BARNES; *Dermatology*, in the Text-books of TILBURY FOX, LIVEING, DUHRING, R. CROCKER, and M. MORRIS; *Medical Electricity*, in DE WATTEVILLE or POORE; *Medical Ophthalmoscopy*, in GOWERS' Handbook. For the M.D. Examination, the candidate will do well to extend his reading to the better-known monographs, such as those of MURCHISON on Continued Fevers and on Diseases of the Liver; GOWERS, ROSS, CHARCOT, and WILKS on Diseases of the Nervous System; BALFOUR, BYROM BRAMWELL, and WALSHE on Diseases of the Heart; POWELL and WALSHE on Diseases of the Lungs; RALFE, W. ROBERTS, and DICKINSON on Diseases of the Kidney; E. SMITH, GOODHART, or the recent works of ASHBY and JONES and of A. MONEY, on Diseases of Children.

In the foregoing lists we have mostly indicated more than one work upon a subject, for it is of course impossible to make a single selection from among so large a number of excellent works. A certain amount of choice must be left to the student himself, who will do well to be guided in this respect by the opinion of his teacher in the particular subject. Since it is impossible as well as undesirable for him to be too discursive in his reading during his student days, he may well resolve to devote such leisure as may happen to him in the future to making the acquaintance of works which will afford not only instruction but pleasure in their perusal.

BRITISH QUALIFICATIONS ABROAD.

THOUGH, of course, the majority of newly-qualified practitioners look forward to spending their lives in Great Britain, a very appreciable minority, for one reason or another, find themselves, either from the very commencement of their careers or at some later period—perhaps towards the decline of life,—impelled to leave the mother country and to begin practice either in some one of the numerous British possessions or in foreign countries. As a British diploma cannot be expected, any more than the Queen's writ, to "run" quite all over the globe, and as a good deal of inconvenience is sometimes caused by uncertainty as to how far it is available, we propose to offer a short account of the regulations regarding the status of a British registered medical practitioner who may seek to practise in the colonies or in foreign countries. Speaking generally, it may be said that no difficulty need be anticipated in any of the colonies (Malta, perhaps, excepted) beyond the payment of a fee, and possibly a short delay.

Australia.—In all the Australian colonies the Medical Board must be first communicated with and the diplomas produced. It is generally necessary also to produce some evidence that the applicant for registration is really the person referred to in the diplomas, and the Board may take means of satisfying itself on this point. There is in some of the colonies a fee of £1 1*s.* to pay. In Western Australia the Board may examine and register an unqualified man.

Tasmania.—Here there is a Court of Medical Examiners, whose duty it is to examine the diplomas of applicants. The fee is not mentioned in the statute.

New Zealand.—There is no Medical Board here. The official to whom application must be made is the Registrar of Births, Deaths, and Marriages of any of the chief towns. The diplomas must be produced, and a copy certified to by a Justice of the Peace left with him. An advertisement must also be inserted in the *New Zealand Gazette*. The fees amount to £1 5*s.*

Fiji.—The Chief Medical Officer must be applied to for registering the name. There appears to be no fee.

Ontario.—Application has to be made to the Registrar of the Council of the College of Physicians and Surgeons, who must be satisfied with the genuineness of the diploma. An initial fee not exceeding $10 and an annual fee not exceeding $3 have to be paid, the applicant thus becoming a member of the College.

Quebec.—Application must be made to the Registrar of the Provincial Medical Board. The act of registration includes the entry of the name as a member of the College of Physicians and Surgeons. The regulations are much the same as in Ontario.

New Brunswick.—The Council of Physicians and Surgeons are applied to, and the diplomas &c. presented for inspection. There is a fee of $10, which also serves to cover the expenses of examination in the case of applicants without a diploma.

Nova Scotia.—Application to be made to the Secretary of the Provincial Board, who acts as Medical Registrar. The fee is $20.

North-West Territory.—Here the Lord-Lieutenant acts as Registrar. The fee is $5.

Prince Edward's Island.—There is a Board of Examiners, who examine diplomas and charge a fee of 30*s.*

Newfoundland.—There is no medical legislation.

Manitoba.—Application has to be made to the Registrar of the College of Physicians and Surgeons. The fee does not exceed $5.

British Columbia.—The diplomas and certificate of registration in Great Britain have to be produced to the Medical Council and an affidavit made before a justice of the peace. A fee of $10 has to be paid, and a yearly tax of the same amount. All persons not registered in Great Britain, even

Digitized by Google

though they may have Canadian diplomas, have to pass an examination and to pay $100.

Barbadoes. — Application to be made to the Medical Assessors; fee 5*s.*

Trinidad.—The Secretary and Treasurer of the Medical Board acts as Registrar. Applicants have to prove their qualifications, and also to show that they bear a good character. All registered persons are members of the Medical Board. There is no fee.

St. Vincent.—Application to be made to the Registrar of the Medical Board. Fee £5.

St. Lucia.—Application to be made to the Chief Clerk in the Government Office. There is no fee.

British Honduras, the *Bahamas*, *Antigua*, *Dominica*, and *Tobago.*—No formality required.

British Guiana.—Application to be made to the Secretary of the Medical Board. Qualifications which have not been registered in Great Britain may be recognised.

Jamaica.—The Registrar-General acts as Medical Registrar. A declaration has to be made before a Justice of the Peace, and the diplomas are initialled by him. The fee is £1. Unqualified persons can be examined by the Medical Council. Fee £11 11*s.*

Grenada —Application has to be made to the Clerk of the Colonial Secretary. There is then a delay of a fortnight. The fee is £1.

Bermuda.—The Governor in Council gives permission to practise on the production of diplomas. There is no fee.

Hong Kong.—The Medical Board examines the qualifications of applicants. A declaration has to be made before a magistrate. The fee is $5.

Cape of Good Hope.—The Colonial Medical Committee examines the diplomas of applicants. The Colonial Secretary will then grant a licence to practise. There is no fee.

Natal.—There is a Medical Board, to which body application must be made and a copy of a declaration before a magistrate produced. The fee is £1 15*s.*

India, Ceylon, and the Straits Settlements.—Practice is free.

Gibraltar.—Diplomas must be produced to the Governor. There is no fee.

Mauritius.—No fees are required.

Sierra Leone.—Practice is free.

Turning now to the question of practice in foreign countries, it must of course be evident that in them more difficulties are likely to be thrown in the way of a British practitioner than in the colonies. Indeed, in the majority of the more important countries an examination of a tolerably strict character has to be passed before applicants, however well qualified, can obtain leave to practise. In most of the States of the American Union, however, British diplomas can be registered.

In *Italy* qualified men who confine their practice to their own countrymen are not interfered with, though, in order to practise generally, the M.D. of an Italian University must be taken.

Very different is the case in *Switzerland*, where an English doctor staying at a hotel for a night can scarcely prescribe for a fellow-traveller without contravening the law. A great deal of jealousy is evinced by Swiss medical men of English practitioners, and every effort is made to prevent their practising. In this feeling the Swiss hotel-keepers, who look largely to English physicians to send them guests, do not at all concur, so that there is a constant struggle between the doctors and the hotel-keepers regarding the exclusion of British practitioners. In order to obtain a licence, a tolerably severe examination—the State examination—has to be passed in French or German at one of the universities: Berne, Basle, Zurich, or Geneva.

In *France*, applicants must either pass the Doctorate at one of the Medical Faculties—Paris, Montpellier, Lyons, Bordeaux, Nancy, or Lille; or a simpler examination—that for qualification as "Officier de Santé"—at the medical school for the department in which he proposes to live, this minor qualification only holding good for the particular department, while the Doctorate holds good for the whole of the French dominions. Applicants should apply to the Minister of Public Instruction, forwarding their diplomas. Sometimes, especially when the applicant is an M.D. of high standing, he is given the diploma of "Officier," and usually he is exempted from portions of the examination. Although the practice of unauthorised persons is technically illegal, an English practitioner who confines himself to practising amongst his own countrymen is, we believe, if he does not obtrude himself in any objectionable way, very unlikely to run the same risk of prosecution as he would in Switzerland.

In *Germany* the State Examination, which is severe, must as a rule be passed. Occasionally exemption may be obtained.

In *Austria* it is necessary not merely to pass the examinations for the degree of Doctor of Medicine of an Austrian university but to become an Austrian subject. Strong influence at Court might perhaps succeed in getting an exception made, but, practically speaking, Austrian territory, which of course includes the Tyrol, seems to be shut off from foreign practitioners.

In *Russia* the State Examination for *Vrach* (medical practitioner) has to be passed. When the applicant holds a foreign M.D. of high value, the Minister of Education may permit the examination to be confined to reading and defending a somewhat elaborate dissertation or thesis.

In *Holland*, *Denmark*, *Sweden*, and *Norway*, a severe State examination must be passed at a university. Under very special circumstances exemption might perhaps be obtained—at least in Norway.

In *Belgium* an examination must be passed before a Central Board of Examiners by all who have not obtained the M.D. from one of the two State universities, Ghent or Liège.

In *Spain* recognition can usually be obtained for British diplomas, but there is frequently considerable delay. Application should be made through the British Minister.

In *Portugal* a State examination must be passed at one of the medical schools. This requires a good knowledge of the vernacular, but it is incumbent on those who wish to practise in Portugal or Madeira.

In *Greece* there is an examination, but it may be passed in English or French.

In *Roumania* there is a *vivâ-voce* examination.

In *Turkey* there is an examination, with a fee of £4 10*s.*, and there is frequently a good deal of delay.

Digitized by Google

In *Chili*, *Brazil*, and the *Argentine Republic*, examinations have to be passed, the severity of which may be, under some circumstances, considerable.

A FEW WORDS OF WARNING.

THE introductory lectures usually place before the embryo doctor the dignity of thought and elevation of purpose that should be the aim of every member of the profession. It is well to be encouraged at times to realise that "man does not live by bread alone"; none the less, however, an aspirant should be allowed to see some of the shadows of the picture before making a choice. There is no disguising the fact that the medical profession is overcrowded, and becoming more so every day. In the Church the would-be curate must find a vacancy ere a bishop will ordain him; in the army and navy only as many candidates are selected as there are vacancies. To the practice of medicine there is no limit of numbers. Moreover, the mode of entering the profession seems to be designed on the plan of an elephant kraal, tapering from a broad beginning, in an easy Arts examination, to a narrow ending in difficult professional ones. This easy beginning lures many. For several years, year by year, 1200 doctors have stepped into the ranks, while only 600 have laid down their arms.

The natural result of over-competition has taken place. Pleasant practices and remunerative practices daily become harder to get and harder to keep. Even in these it is increasingly difficult to make a provision against the day of sickness and old age. Below the level of the successful ones are strugglers who barely keep their heads above water. The constant appeals in our columns bear sad record to the frequency with which wife and children are left utterly destitute. It is not merely—or even mainly, we would say—in lessened incomes that hard times have made themselves felt. In the lower ranks of the profession small incomes have been the rule all along, but now there is in addition a great change for the worse in the matter of status, personal comfort, and duration of work. Friendly societies combine, for instance, and pay a doctor. Formerly he accepted the club; now the club selects him. His remuneration is often very fair, but he is a servant instead of an independent man, and his comfort is never considered. He must work not only in the day, but every evening until ten or eleven, Sundays included. Life for him is one weary monotony of toil. The labouring classes, once accustomed to obtain such conveniences for a trifling payment of a penny a week or less, naturally become more exacting all round. Most of the discomforts of a medical man's life are quite unnecessary. Four-fifths of the late messages, which involve a second round in the same direction or an evening visit after a weary day, are not required because illness has supervened suddenly, but because the patient has postponed sending, hoping to avoid the necessity altogether. The same remark applies to Sunday work. Hardly any of it would be necessary if people took more pains to spare medical men. Perhaps the remedy for this state of things lies in a more efficient combination to protect common interests. Possibly, if medical men had offices, as is customary in America, people would learn to keep to business hours or pay accordingly for extra services No one expects a bank to keep open beyond its hours to save a careless customer from financial ruin. Let us hope that, as medicine becomes more honoured, these petty worries will be reduced to the minimum that is really unavoidable in so uncertain a calling. The remedy for the lack of financial prosperity is not so easy to see, especially as medical men are almost obliged to keep up appearances, and hence the public believe them to be better off than they really are. Nor have the members of any other learned profession to collect their income direct in driblets from the poor. The highest judge on the bench or the greatest general in the land is, of course, in part paid by the poor, but indirectly. No doubt both judge and general would often forego part of their income, as medical practitioners frequently do, if they had to go to poor houses in time of sickness for doles of half-a-crown instead of having a tax-gatherer to do it for them. Another difficulty of the medical career is the personal nature of any reputation enjoyed. If a schoolmaster makes a name, he can add to his staff of assistant masters; an architect can take apprentices, a lawyer articled clerks; a shopkeeper can multiply assistants; and in every case the juniors can add largely to their chief's income. To a member of the medical profession reputation merely means that extra income can be won, but solely by increased physical and mental efforts, under which too often he breaks down in a few years. Such are some of the dark shades in the picture.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Digitized by Google

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council, and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, and shall enter therein the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and *evidence that he has commenced medical study*. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent — have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before December 31st, in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Act (1858), and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit exceptions to this recommendation. The regulations for preliminary general education are as follows:—

No person shall be allowed to be registered as a medical student unless he shall have previously passed (at one or more examinations) a preliminary examination in the subjects of general education as specified in the following list:—1. English Language, including Grammar and Composition. 2. Latin, including Grammar, Translation from specified authors, and Translation of easy passages not taken from such authors. 3. Elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first book of Euclid, with easy questions on the subject-matter of the same. 4. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics. 5. One of the following optional subjects:—(*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other Modern Language, (*f*) Logic, (*g*) Botany, (*h*) Zoology, (*i*) Elementary Chemistry.[1]

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 1, George-square, Edinburgh.—R. L. Heard, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

[1] In the case of students in Universities with a prolonged curriculum, where the examination in Mechanics required for their degree is taken at a more advanced period of study than before commencing medical education, registration can be effected only on having passed the examination in Mechanics, but their registration may be then antedated to the period at which the Preliminary was passed.

I.—UNIVERSITIES IN THE UNITED KINGDOM.

The following is a list of Examining Bodies whose examinations fulfil the conditions of the Medical Council as regards preliminary education, and have been recognised as entitling to registration as a medical or dental student; provided that the Elementary Mechanics of Solids and Fluids, comprising the elements of Statics, Dynamics, and Hydrostatics, is shown to have been included in the examination:—

University of Oxford.—Junior Local Examinations; Certificate to include Latin and Mathematics, and also one of these optional subjects—Greek, French, German. Senior Local Examinations; Certificate to include Latin and Mathematics. Responsions. Moderations. Examination for a Degree in Arts.

University of Cambridge.—Junior Local Examinations; Certificate to include Latin and Mathematics, and also one of these optional subjects—Greek, French, German. Senior Local Examinations; Certificate to include Latin and Mathematics. Higher Local Examinations. Previous Examination. Examination for a Degree in Arts.

University of Durham.—Examination for Certificate of Proficiency. Examination for students at the end of their first year. Examination for a degree in Arts.

University of London.—Matriculation Examination. Preliminary Scientific (M.B.) Examination. Examination for a Degree in Arts or Science.

Victoria University.—Preliminary Examination; Latin to be one of the subjects. Entrance Examination in Arts, to include all the subjects required.

University of Edinburgh.—Local Examinations (Junior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Local Examinations (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Preliminary Examination for Graduation in Science or Medicine and Surgery. Examination for a Degree in Arts.

University of Aberdeen.—Local Examinations (Junior Certificate); Certificate to include all the subjects required. Local Examinations (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Preliminary Examination for Graduation in Medicine or Surgery. Examination for a Degree in Arts.

University of Glasgow.—Local Examinations (Junior Certificate); Certificate to include all the subjects required. Local Examinations (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Preliminary Examination for Graduation in Medicine or Surgery. Examination for a Degree in Arts.

University of St. Andrews.—Local Examinations (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Local Examinations (Junior Certificate), to include all the subjects required. Preliminary Examination for Graduation in Medicine or Surgery. Examination for a Degree in Arts.

University of Dublin.—Public Entrance Examination. General Examination at end of Senior Freshman year. Examination for a Degree in Arts.

Queen's University in Ireland.—Local Examinations for Men and Women; Certificate to include all the subjects required by the General Medical Council. Entrance or Matriculation Examination. Previous Examination for B.A. Degree. Examination for a Degree in Arts.

Royal University of Ireland.—Matriculation Examination.

Oxford and Cambridge Schools Examination Board.—Certificate to include the following subjects, an adequate knowledge of English Grammar and Orthography, as shown in the course of the examination, to the satisfaction of the examiners, being held as conforming to the requirements of the Medical Council in regard to those subjects: (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first two books of Euclid; (*d*) Latin, including Translation and Grammar; (*e*) Also one of these optional subjects—Greek, French, German.

Digitized by Google

II.—OTHER BODIES NAMED IN SCHEDULE A TO THE MEDICAL ACT.

Apothecaries' Society of London.—Examination in Arts.
Royal Colleges of Physicians and Surgeons of Edinburgh. Preliminary (combined) Examination in General Education.
Faculty of Physicians and Surgeons of Glasgow.—Preliminary Examination in General Education.
Royal College of Surgeons in Ireland.—Preliminary Examination; Certificate to include Mathematics.

III. — EXAMINING BODIES IN THE UNITED KINGDOM, NOT INCLUDED IN SCHEDULE A TO THE MEDICAL ACT (1858).

College of Preceptors.—Examination for a First Class Certificate, or Second Class Certificate of First or Second Division, Algebra, Geometry, Latin, and either a Modern Language, or Greek or Chemistry, or Botany or Zoology, having been taken.
Queen's College, Belfast.—Matriculation Examination.
Queen's College, Cork.—Matriculation Examination.
Queen's College, Galway.—Matriculation Examination.
Intermediate Education Board of Ireland.—Junior Grade Examination, Middle Grade Examination, Senior Grade Examination (Certificate in each case to include all the subjects required).
St. David's College, Lampeter.—Responsions Examination, to include all the subjects required.
Educational Institute of Scotland.—Preliminary Medical Examination.
Pharmaceutical Society of Great Britain.—Preliminary and Minor Examinations (*pro tanto*).
Pharmaceutical Society of Ireland.—Preliminary Examination (*pro tanto*).
Scotch Education Department.—Leaving Certificates in each Grade and in Honours.

REGULATIONS OF THE MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

There are two degrees in Medicine, B.M. and D.M., and two degrees in Surgery, B.Ch. and M.Ch., and a diploma in Public Health.

The B.M. and B.Ch. degrees are granted to those members of the University who have passed the Second Examination. Graduates in Arts (B.A. or M.A.) are alone eligible for these two degrees. After the degree of B.A. is obtained, the degrees of B.M. and B.Ch. may be obtained by passing the following examinations: — 1. Preliminary. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, and Materia Medica with Pharmacy.

The degree of D.M. is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of B.M. subsequently to the end of Trinity Term, 1886, provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations.

The diploma in Public Health is granted only to Bachelors of Medicine of the University who have passed an examination in Hygiene, Sanitary Law, Sanitary Engineering, and Vital Statistics.

The First Examination for the degrees of B.M. and B.Ch. and the Examination in Materia Medica and Pharmacy may be passed as soon as the Preliminary Examination in Medicine has been completed. Organic Chemistry may be taken on a separate occasion, but before Human Physiology and Anatomy. The two last-named subjects must be taken together. For exemptions see *ante*.

The Second Examination may be taken after the completion of the first. Materia Medica and Pharmacy, if not already passed, may be offered on a separate occasion, but before the remaining subjects, which must be taken together.

The Professional Examinations in Medicine are held once a year in Trinity Term, the second before the first.

Instruction in the subject-matter of Responsions, Moderations, and the various literary schools is given by the tutors and lecturers of the Colleges and Halls. In Natural Science, the professors of the University and their assistants deliver regular courses of lectures and conduct classes for practical instruction in the laboratories of the Museum and Botanic Garden in each term. In addition, several Colleges possess tutors in Science, and in two or three instances laboratories as well. In Medicine, instruction in Organic Chemistry is given once a year. Physiology, Physiological Chemistry, and Histology are taught by the Wayntlete Professor of Physiology and his assistants; Human Anatomy by the University lecturer in that subject, under whose control is placed the department for dissection. Provision for the teaching of Materia Medica is being made. Instruction and demonstrations in Physical Diagnosis and Regional Anatomy are given in each term at the Radcliffe Infirmary. Clinical lectures in Medicine and Surgery are also delivered by the two Lichfield lecturers of the University, a physician and a surgeon of the infirmary respectively; but as full provision does not exist for the teaching of the subjects for the Second Professional Examination (except Materia Medica), it is necessary for a student to obtain his knowledge elsewhere. The Radcliffe Library at the Museum contains a vast collection of scientific and medical literature, available for study and consultation by students.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average annual value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination, every year by some, from time to time by other, Colleges. Notices of vacancy &c. are published in the *University Gazette*. In February there is competed for annually, by those who have obtained a first class in any school (Moderations or Final), or a Scholarship or Prize open to general competition in the University, one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study, and take the degree of B.M. Oxon. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology.

More detailed information may be obtained from the University Calendar; the Examination Statutes, 1887, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; and from the Secretary, Medical Department, University Museum.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may, and should if possible, be done immediately on coming into residence in October, or, what is better, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study

Digitized by Google

and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required. This time may be spent in Cambridge or elsewhere. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed (say) the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection, &c., is unusually abundant.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These may be taken together or separately. The *second* in Human Anatomy and Physiology, and in Pharmaceutical Chemistry. These may be taken together or separately. The *third* may be also taken in two parts—viz., (1) Principles and Practice of Surgery (with Operative and Clinical Surgery) and Midwifery and Diseases of Women, and (2) Pathology, Principles and Practice of Medicine, Elements of Hygiene, and Medical Jurisprudence. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories.

Previously to the first examination, Lectures must have been attended on Chemistry (with manipulations). Previously to the second examination, the student must have attended Lectures on Human Anatomy and Physiology, have dissected for six months, and attended Hospital Practice six months. Previously to the first part of the third examination, he must have attended Lectures on Pathology, the Principles and Practice of Surgery and Midwifery, twenty cases of Midwifery, and produce a certificate of proficiency in Vaccination, and must also have acted as House Surgeon or Dresser for six months, and have gone through a course of instruction in Practical Surgery. Previously to the second part of the third examination, he must have attended Lectures on the Principles and Practice of Physic, the Physiological Action and Therapeutic Uses of Drugs, and Medical Jurisprudence; also the Medical and Surgical Practice of a Hospital, with Clinical Lectures, for three years, and have been Clinical Clerk for six months. Before proceeding to the degree of M.B. the candidate must compose an original thesis on some one of the subjects prescribed for the several examinations, and defend the same in public before the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of the third M.B. examination, candidates who have passed that examination are admitted to the degree of *Bachelor of Surgery* (*B.C.*) without separate examination, and without keeping an Act.

The degree of *Doctor in Medicine* may be taken three years after that of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools, with *vivâ-voce* examination; and an extempore Essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

For the degree of *Master in Surgery* (*M.C.*) the candidate must have passed all the examinations for B.C. two years previously. He is required to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery, and to write an extempore Essay on a Surgical subject.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, and Pharmacy may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on the second Monday in January and the second Monday in June. Candidates must be above sixteen years of age. The fee for the examination is £2. Provincial examinations are appointed by the Senate from time to time at specified centres. The examination appointed for January 13th, 1890, will be held at Birmingham, Cardiff, Glasgow, Leeds, and Portsmouth, as well as at London. That appointed for June, 1890, will be held also at Bangor, Birmingham, Cardiff, Edinburgh, Epsom, Leeds, Liverpool, Manchester, Newcastle-on-Tyne, Nottingham, and Sheffield. Several scholarships, exhibitions, and prizes are associated with these examinations.

The *Preliminary Scientific* (*M.B.*) *Examination* takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates only on the third Monday in January.[2] No candidate will be admitted to this examination until he shall have passed the Matriculation Examination, nor unless he shall have given notice of his intention to the registrar at least one calendar month before the commencement of the examination. Fee for this examination, £5.

Candidates are examined for a Pass or for Honours or Inorganic Chemistry and Experimental Physics; and for a Pass, on General Biology. Candidates for Honours, who have entered for the whole examination, may also be examined for Honours in Botany and Zoology.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University. 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in his professional studies during four years subsequently to passing the Preliminary Scientific Examination[3] at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year, once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry, in applying tests for discovering the adulteration of articles of the materia medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the registrar at least four weeks before the commencement of the examination. Fee for this examination, £5.

Candidates at the July examination are examined for a Pass or for Honours in each of the following subjects: (1) Anatomy, (2) Physiology and Histology, (3) Organic Chemistry, (4) Materia Medica and Pharmaceutical Chemistry. The Pass and Honours questions at the July examination will be given on one and the same paper, and will be divided into (*a*) Pass questions and (*b*) Honours questions. Candidates will be allowed to answer questions out of either or both groups; but no credit will be given for more than half of the total number of questions, of which half, in the

[2] Candidates for the degree of M.B. are required by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and are recommended to devote a preliminary year to preparation for it, according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

[3] Candidates who passed the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their professional studies, as heretofore, from that examination.

Digitized by Google

case of candidates for Honours, one-third must be taken from group (*b*). Immediately after the written examination, candidates desiring to proceed in Honours in any subject or subjects must give notice to the Registrar, in order that, when necessary, special provision may be made for the practical examinations. A candidate who enters for, but fails to obtain, Honours in any subject, may be recommended by the examiners for a Pass in that subject, if they are satisfied that he has shown such a competent knowledge thereof as is required by the regulations for the Pass Examination.

M.B. Examination.[4]—The M.B. Examination takes place twice in each year—once for Pass and Honours, commencing on the last Monday in October; and once for Pass candidates only, commencing on the first Monday in May. No candidate will be admitted to this examination within two academical years of the time of his passing the Intermediate Examination unless he be a registered medical practitioner of not less than three years' standing, in which case he must produce a certificate of having gone through the required course of training at some time previously. Every candidate must produce certificates to the following effect:—1. Of having passed the Intermediate Examination. 2. Of having, subsequently to having passed the Intermediate Examination, attended a course of lectures on each of two of the subjects enumerated in Section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The fee for this examination is £5.

Candidates will be examined in the following subjects: General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry.

Any candidate who has passed the M.B. Examination, beginning in October, may be examined at the Honours Examination next following the M.B. Examination at which he has passed for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine, they are conducted by means of printed papers, but the examiners will not be precluded from putting *viva-voce* questions upon the written answers.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed for Honours in Surgery. The examination takes place on Tuesday in the week following the Pass Examination, and is conducted by means of printed papers.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University.[5] 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University, (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. Fee for this degree, £5. The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Mental Physiology, especially in its relations to mental disorder, and in Surgery.

Any candidate for the degree of M.S. may transmit to the Registrar, not later than October 1st, a printed Dissertation, Thesis, or Commentary, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Surgical Science, embodying the result of independent research, or showing evidence of his own work, whether based on the discovery of new facts observed by himself, or of new relations of facts observed by others, or generally tending to the advancement of Surgical Science. If the Dissertation, or Thesis, or Commentary, be approved by the examiners, the candidate will be exempted from the written and clinical examination in Surgery, subject to such examination upon the Thesis as the examiners at their discretion may think fit.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University, or, if he enter for State Medicine, during two years to State Medicine; or (*b*) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, or during one year to State Medicine as above, and having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

Fee for this degree, £5. The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Mental Physiology, especially in its relation, to mental disorder, and in Medicine.

The regulations with regard to Theses are similar to those obtaining in connexion with the examination for the M.S.

UNIVERSITY OF DURHAM.

Three Licences and four Degrees in Medicine are conferred—viz., Licences in Medicine, in Surgery, and in Sanitary Science; and the Degrees of Bachelor in Medicine,

[4] Any candidate for the M.B. Examination who has passed the Intermediate Examination under the former regulations will be required to have also passed the examination in Physiology at some previous Intermediate Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

[5] Candidates who have obtained the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

Digitized by Google

Bachelor in Surgery, Master in Surgery, and Doctor in Medicine.

For the degree of *Bachelor in Medicine* (*M.B.*) there are three professional examinations: the first being held in April (in 1890, commencing on the 14th) and September (in 1890, commencing on the 8th); the second in April (in 1890, commencing on the 21st) and September (in 1890, commencing on the 15th); and the third in December (in 1889, commencing on the 2nd) and June (in 1890, commencing on the 16th).

The subjects for the First examination are—Elementary Anatomy and Elementary Physiology, Chemistry with Physics, and Botany. Every candidate must produce the following certificates:—(1) Of registration as a medical student. (2) Of attendance on the following courses of lectures: Anatomy, Physiology, Chemistry with Physics, and Practical Anatomy (Dissections), each six months; Botany and Chemistry, each three months.

The subjects for the Second examination are—Anatomy, Physiology, and Materia Medica with Pharmacy. For it the following certificates are necessary:—Lectures, &c.: Anatomy, Physiology, and Practical Anatomy (Dissections), second courses of six months each; Materia Medica, Practical Physiology, and Practical Pharmacy, courses of three months each. The candidate must also produce a certificate of his having passed the first examination for the M.B., or the first examination of the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, together with the extra examinations in Chemistry and Botany of the University of Durham.

The subjects for the Third examination are—Medicine, Surgery, Pathology, Therapeutics, Midwifery and Diseases of Women and Children, Medical Jurisprudence, and Public Health. For it candidates must produce the following certificates—viz.: 1. Of being not less than twenty-one years of age. 2. Of good moral character. 3. Of having passed one of the following examinations in Arts: (*a*) The Examination for Graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), Queen's College (Kingston), Victoria (Manchester), and Royal (Ireland). Or (*b*) the Preliminary or Extra-professional Examination for Graduation in Medicine at one of the following universities—Cambridge, London, Edinburgh, Glasgow, St. Andrews, Aberdeen, Queen's (Ireland), Victoria (Manchester), and Royal (Ireland), provided that the candidate in obtaining the certificate shall have satisfied the examiners in Greek. Candidates holding a certificate which does not include Greek may offer themselves for examination in that subject alone at the examination for the certificate for Proficiency in General Education at Durham, or at the Preliminary Examination in Arts for the degrees in Medicine above mentioned. This regulation will apply to all candidates entering for the degrees in Medicine on or after October 1st, 1888. Or (*c*) the Preliminary Examination in Arts qualifying for the Membership of the Royal College of Physicians of London or for the Fellowship of the Royal College of Surgeons of England. Or (*d*) the Preliminary Examination in Arts for the degrees in Medicine of the University of Durham (in 1890, commencing on April 1st and Sept. 30th). 4. Of attendance on the following course of lecurets—viz.: Medicine and Surgery, each two courses of six months; Public Health, one course; Forensic Medicine, Midwifery and Diseases of Women and Children, and Pathology, each one course of three months; Clinical Medical and Clinical Surgical Lectures, each two winters and two summers; Medical Hospital Practice and Surgical Hospital Practice and Post-mortem Demonstrations, each three winters and two summers; Medical Clinical Clerking and Surgical Dressing, each six months; Clinical Obstetrics, three months; attendance on not less than twenty cases of Midwifery, and instruction in Vaccination.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom, will be exempt from the First Examination of the University, except in the subjects of Chemistry with Physics and Botany. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery* (*B.S.*) every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham, and must have attended one course of lectures on Operative Surgery, and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery* (*M.S.*) candidates must not be less than twenty-four years of age, must have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The subjects of examination are: Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, and Clinical Surgery.

For the degree of *Doctor of Medicine* (*M.D.*) candidates must not be less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in Medical and Surgical Practice. Each candidate will be required to write an Essay on some Medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the registrar of the College.

THE VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds.

Three degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine and of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required—(1) to have matriculated in the University; and (2) to pass (either *before* or *after* matriculation) an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[6]

Degree of Bachelor of Medicine.—Before admission to the degree of M.B. candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than four years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the Preliminary Examination in Science. All candidates for the degree of Bachelor of Medicine are required, after matriculating, to satisfy the examiners in the several subjects of the following examinations: the Preliminary Examination in Science, the Intermediate Examination, and the Final Examination.

The Preliminary Examination in Science.—The subjects of examination are as follows:—(1) Chemistry; (2) Elementary Biology; (3) Physics; Candidates for the Preliminary Examination in Science must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects.

The Intermediate Examination. — The subjects of examination are as follows:—(1) Anatomy; (1) Physiology (including Physiological Chemistry and Histology); (3) Materia Medica and Pharmacy. Candidates for the Intermediate Examination are required to have passed the Preliminary Examination in Science, and to have attended courses of instruction in Anatomy for one winter session, in Physiology for two winter sessions (but one session will be

[6] The examinations at present recognised are:—1. The Preliminary Examination of the Victoria University, provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions and Moderations of the University of Oxford. 5. The Leaving Certificate Examination of the Oxford and Cambridge Boards, provided that it include Latin, English, Mathematics, and Elementary Mechanics. 6. The Final Examination for Graduation in Arts of any University in Great Britain and Ireland.

Digitized by Google

accepted provided that a full course has been attended by the candidate), and in Materia Medica and Pharmacy for one summer session. The certificates must show (1) that Dissection has been practised during two winter sessions and one summer session at least; (2) that laboratory instruction has been received in Physiology; (3) that practical instruction has been received in Materia Medica and Pharmacy.

The Final Examination.—The subjects of examination are: (1) Surgery—Systematic, Clinical, and Practical; (2) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children; (3) Forensic Medicine and Toxicology, and Public Health; (4) Pharmacology and Therapeutics; (5) Obstetrics and Diseases of Women; (6) General Pathology and Morbid Anatomy. Candidates may present themselves for examination in all the above subjects on the same occasion, provided they have completed the *fourth year* of medical study, in accordance with the regulations of the University. Candidates may, however, present themselves for examination in two or three only of these subjects, provided they have completed the *fourth winter* of medical study in accordance with the regulations of the University, but must satisfy the examiners in *all* the subjects so selected before presenting themselves in the remaining subjects of examination. Before presenting themselves for the Final Examination, candidates are required to have passed the Intermediate Examination, and to furnish certificates of having attended courses of instruction approved by the University, in a college of the University, or in a medical school recognised for this purpose by the University, in the subjects in which they offer themselves for examination. The following certificates will be required:—1. In Medicine and Surgery, of having attended the medical and surgical practice of a hospital or hospitals, approved by the University, during at least three years, of which years two at least must be subsequent to the date of passing the Intermediate Examination, except when exemption has been granted by the General Board of Studies, after report from the Departmental Board of Medical Studies. 2. In Pathology and Morbid Anatomy, of having attended during at least twelve months demonstrations in the post-mortem theatre of a hospital. 3. In Obstetrics, of having attended, under proper supervision, at least twenty cases of labour. 4. In Diseases of Women, of having, during at least three months, received in either a general or a special hospital, approved by the University, such clinical instruction in the diseases peculiar to women as shall be approved by the University. 5. Of having acquired proficiency in Vaccination. 6. Of having acted as a dresser for six months in the surgical wards, and as a clinical clerk for six months in the medical wards, of a hospital recognised by the University. 7. Of having attended courses of instruction, approved by the University, in a college of the University, or in a medical school or hospital recognised for this purpose by the University, in the following subjects of examination:—(*a*) Systematic Surgery—one winter session; Practical Surgery—one winter session; Clinical Surgery—two years of Clinical Lectures. (*b*) Systematic Medicine—two winter sessions; Clinical Medicine—two years of Clinical Lectures. (*c*) Forensic Medicine—one summer session; Public Health—one summer session. (*d*) Pharmacology and Therapeutics—one winter or one summer session. (*e*) Obstetrics and Diseases of Women—two summer sessions or one winter session. (*f*) General Pathology and Morbid Anatomy—one winter and one summer session.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. Candidates for the degree of Doctor of Medicine are required to present a printed Dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his dissertation, after report from the Departmental Board of Medical Studies, shall have been recommended by the General Board of Studies to the Council for acceptance in that behalf. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgical Pathology; (3) Practical Surgery, including the performance of operations on the dead body; (4) Clinical Surgery; (5) Ophthalmology.

UNIVERSITY OF EDINBURGH.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine.

No one is admitted to the degrees of Bachelor of Medicine and Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.[7]

Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—(*a*) That he has studied each of the following departments of medical science—namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures;[8] Practical Chemistry, three months; Practical Midwifery—(1) that he has attended at least twelve cases of labour under the superintendence of a registered medical practitioner, or (2) that he has attended six such cases, and also has attended, for at least three months, the practice of a midwifery hospital in which practical instruction is regularly given; Clinical Medicine and Clinical Surgery,[9] courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, and Natural History (including Zoology), during courses including not less than fifty lectures. (*b*) That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. (*c*) That he has attended, during a course of not less than fifty hours' instruction, the class of Practical Materia Medica and Pharmacy in the University of Edinburgh, or a similar class conducted in a university or recognised school of medicine, or a similar class conducted at the laboratory of a hospital or dispensary, or elsewhere, by a teacher recognised by the University Court; or that he has been engaged by apprenticeship for not less than two years with a registered medical practitioner, or a member of the Pharmaceutical Society of Great Britain, or a member of the Pharmaceutical Society of Ireland, or a pharmaceutical chemist, or chemist and druggist, registered under the provisions of the Act for Regulating the Qualifications of Pharmaceutical Chemists, 1852, the Pharmacy Act, 1868, or the Pharmacy Act (Ireland), 1875, in the *bonâ-fide* compounding and dispensing of drugs, and the preparation of their officinal and other preparations under his superintendence. (*d*) That he has attended, for at least six months, by apprenticeship or otherwise, the outdoor practice of a hospital, or the practice of a dispensary physician, a surgeon, or a member of the London or Dublin Society of Apothecaries. (*e*) That he has attended, during courses of not less than fifty hours' instruction, classes of Practical Physiology and Practical Pathology in the University of Edinburgh, or in a recognised university or school of

[7] No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures, in conformity with the requirements of this section. Three months' courses on Materia Medica, Pathology, and Midwifery do not qualify.

[8] Certificates of attendance on Practical Anatomy must express not only the number of months engaged in dissection, but the names of the parts dissected, and the degree of care with which the dissections have been made. Students are recommended not to appear for an examination in Anatomy with a view to a degree until they have dissected the human body at least once.

[9] The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

Digitized by Google

medicine, or upon classes thereof, conducted by a teacher recognised by the University Court.

Students of Medicine in the London Schools, and in the school of the College of Surgeons in Dublin, can obtain there two *anni medici* out of the four required for the Edinburgh degrees in Medicine. Courses of lectures in these schools, and the courses of the medical teachers and of the science teachers in King's College and in University College, London, in the subjects of graduation, are regarded as equivalent to lectures on the corresponding subjects in this University, except Materia Medica and Midwifery, which when only three months' courses are not received as equivalent. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (*a*) full winter courses on any two of the following subjects—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (*b*) on one such course and two three months' courses on any of the following subjects—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in *a*, attendance on a third course, although unnecessary to constitute an *annus*, will also be accepted. The other subjects and the additional courses, not given in London or Dublin, necessary for the degrees of the University, require to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance at a qualified hospital along with a course of Practical Anatomy. But in a provincial school where there are two or more lecturers recognised by this University, a second *annus medicus* may be made by attendance on at least two six months' or one six months' and two three months' recognised courses.

Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine, a declaration in his own handwriting that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be on the day of graduation under articles of apprenticeship to any surgeon or other master. This declaration, along with a statement of studies, accompanied with proper certificates, is appended to the schedule for the Final Examination, and must be signed before the schedule is given in.

Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy and Prescribing), and Pathology; on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; clinically, on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates. Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*. Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of their fourth year.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Master in Surgery, and who is of the age of twenty-four years, and produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and C.M., for at least two years in attendance on a hospital, or in the military or naval medical service, or in medical and surgical practice. Provided always that the degree of M.D. shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degrees of M.B. and C.M., or thereafter, have passed a satisfactory examination on *three* of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, Higher Mathematics, and Natural Philosophy. And provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the Professional Examinations for the degrees of M.B. and C.M. which he may have made a subject of study after having received these degrees.

The fees for M.B. and C.M. are £22. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degree of M.D. and the stamp duty for the latter must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the Professional Examinations, the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August.

The fees for the degrees are £21 for M.B. and C.M., which are obtained together, and £15 for M.D.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant clerk, Matriculation Office, the University.

The First, Second, and Third Professional Examinations are held in April and in October each year, and the Fourth or Final Examination is held annually in June and July.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10*s*.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on the Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

A diploma in Public Health is granted by the University to its graduates in Medicine, after a special examination. The diploma can be entered on the Register of the General Medical Council.

Regulations for the Diploma in Public Health (*D.P.H.*).—Candidates for the diploma must have graduated in Medicine in the University before they receive the diploma; and they must give evidence of having attended a course of instruction in Analytical Chemistry or in Practical Hygiene. The diploma is conferred after an examination in Public Health, held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send their names, with the necessary fee, to the Secretary of the Medical Faculty before the first day of the month in which the examination takes place. The fee for the examination is £3 3*s*. In the event of a candidate failing to pass the examination, a fee of £1 1*s*. will be charged for each subsequent examination for which he may enter. The examination is conducted by the examiners for the medical degrees. The examination is written, oral, and practical. The subjects and scope of the examination are as follows:—1. Physics and Meteorology: The general principles of Physics in so far as they relate to Heat and

Digitized by Google

Ventilation, Water Supply and Drainage; the elements of Meteorology and Climatology; practical exercises in the use of Meteorological Instruments. 2. Chemistry and Microscopy: The Composition and Analysis of Air, Water, and Sewage; the Composition and Adulterations of the more common Foods and Beverages; Diseased and Putrid Food; practical exercises in the Chemical and Microscopical examination of Air, Water, and Foods. 3. General Hygiene: Duties of Medical Officers of Health; Nature and Construction of Dietaries; Construction and Sanitary Arrangements of Houses, Hospitals, Workshops, Factories, Towns, &c., including interpretation of plans; Ventilation, Water Supply, Sewerage, Disposal of Dead; Etiology, Prophylaxis (including Vaccination), and Control of Infectious Diseases; Unhealthy Occupations; practical exercises in examining and reporting on the Construction and Sanitary Arrangements of Houses, &c. 4. Sanitary Law and Vital Statistics: Laws relating to the Public Health of Scotland, England, or Ireland, at the option of the candidate; Laws relating to Vaccination, and Registration of Births, Marriages, and Deaths; Methods and Data of Vital Statistics, mainly in so far as they relate to the birth, marriage, and death rate of communities.

Application for further information should be addressed to the Dean of the Medical Faculty.

The degrees of B.Sc. and D.Sc. are now granted, after examination, in one of several specified departments of Science, to be selected by the candidate. For regulations apply to the Secretary of Science Department.

UNIVERSITY OF ST. ANDREWS.

Two degrees in Medicine are granted—namely, Bachelor of Medicine and Master in Surgery (M.B., C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section on a greater number than ten in any one year. The examinations are held yearly towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims; and where these seem equal, preference will be given to age and priority of application. 3. A portion of the graduation fee (viz., £10 10*s.*), which shall be forfeited should the candidate fail to appear or to graduate at the time appointed. A satisfactory examination, written and *viva voce*, must be passed in the following departments—viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine and Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degree of Bachelor of Medicine and Master in Surgery will be under the following regulations. The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the Medical or Surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates with the Dean of the Medical Faculty, on or before the 25th of March in each year.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Previous Medical Examination.—Candidates for degrees in Medicine, Surgery, and Midwifery are required to pass an examination in Physics, Chemistry, Botany, Comparative Anatomy, Descriptive Anatomy, and Institutes of Medicine (Practical Histology and Physiology), previously to their degree examination.

Bachelor in Medicine.—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same Commencements as that at which he receives his degree of B.A., or at any subsequent Commencements. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures—Anatomy, Practical Anatomy, Chemistry, Materia Medica and Pharmacy, Physiology, Practice of Medicine, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy; three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College; a certificate of personal attendance on Fever cases, with names and dates of cases. Six months' Dissections, three months' Laboratory Instruction in Chemistry, three months' Practical Histology, and one month's instruction in Vaccination are required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows. Fee for the *Liceat ad Examinandum*, £5; for the M.B. degree, £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis or undergo an examination before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study, which includes the following additions to the courses named above for the M.B.: Theory of Surgery, Operative Surgery, Two Courses of Dissections, Ophthalmic Surgery.[10] Candidates are required to perform surgical operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin, of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass an examination in the following subjects:—1. Clinical Surgery; 2. Operative Surgery; 3. Surgical Pathology; 4. Surgery; 5. Surgical Anatomy (on the dead subject); and one of the following optional subjects:—1. Surgery, in one of its recognised branches—viz., Ophthalmic and Aural, Gynæcological, and Dental; 2. Mental Disease; 3. Medical Jurisprudence and Hygiene; 4. Advanced Anatomy and Physiology; 5. Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Bachelor in Obstetric Science.—The candidate for the

[10] Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previously to the creation of the degree of Bachelor in Surgery.

Digitized by Google

B.A.O. Examination must be a Bachelor in Arts, having previously completed the prescribed curriculum of study. The curriculum comprises the following, in addition to the complete course for the M.B.:—Theory and Practice of Midwifery, one course (winter); Practical Midwifery, including Clinical Lectures, six months. The candidate is then required to pass an examination in Practical Midwifery, Gynæcology, and Obstetrical Anatomy. Fee for the degree of Bachelor in Obstetric Science, £1. There is no Liceat fee.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. examinations, and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery.[11] He is then required to pass an examination in the following subjects—1. Practice of Midwifery. 2. Gynæcology. 3. Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. Fee for the degree of Master in Obstetric Science, £5.

University Diplomas.—Candidates for the Diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and four years in Medical Studies.

Diploma in Medicine.—The Medical Course and Examination necessary for the Diploma in Medicine are the same as for the degree of M.B., except that the candidate is not required to attend the Lectures on Botany and Comparative Anatomy, nor to pass the previous medical examination in those subjects. A Diplomate in Medicine, on completing his course in Arts, and proceeding to the degree of B.A., may become a Bachelor in Medicine by attending the Lectures on Botany and Comparative Anatomy, passing the previous medical examination in those subjects, and paying the degree fees. Fee for the *Liceat ad Examinandum*, £5. Fee for the Diploma in Medicine, £5.

Diploma in Surgery.—The Surgical course and examination necessary for the Diploma in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5. Fee for the Diploma in Surgery, £5.

Diploma in Obstetric Medicine.—The course and examination for the Diploma in Obstetric Science are the same as that for the Bachelor in Obstetric Science. Fee for the Diploma in Obstetric Science, £1.

N.B.—Each candidate having completed the prescribed courses of study, passed the requisite qualifying examinations in Medicine, Surgery, and Midwifery, and had conferred on him the corresponding degrees, will obtain from the Senior Proctor a diploma entitling him to be entered on the Register of Medical Practitioners under the Medical Act, 1886.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, Prizes, and Scholarships in this University are open to students of either sex.

Candidates for any degree in this University must have passed the Matriculation Examination. Students from other Universities and Colleges are included in this rule.

The following degrees &c. are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics, Master of Obstetrics; in Sanitary Science, a special diploma; in Mental Disease, a special diploma.

The Medical Examinations, except that for the diploma in Sanitary Science, will be held twice yearly—viz., in April and in October. The examination for the diploma in Sanitary Science will be held in July.

The course for degrees in Medicine &c. is of at least four years' duration. Students who have commenced their medical studies since January 1st, 1884, must furnish evidence of having been registered by the Medical Council as students in Medicine for at least forty-five months before being admitted to the final examination for M.B. No one can be admitted to a degree in Medicine who is not fully twenty-one years of age. All candidates for these degrees are, in addition to attending the lectures and complying with the other conditions to be from time to time prescribed, required to pass the following examinations:—The Matriculation Examination, the First University Examination, the First Examination in Medicine, the Second Examination in Medicine, the Third Examination in Medicine, and the Examination for Primary Medical Degrees.

[11] Existing Graduates in Medicine, of the standing of M.D., are not required to attend this course.

The First Examination in Medicine.—Students may not be admitted to this examination until the lapse of two academical years from the time of their matriculation. They must also have previously passed the First University Examination. The subjects of this examination are: Natural Philosophy, Chemistry, Zoology, and Botany. The examination in each subject will comprise two parts: (1) A written examination; (2) practical work and oral examination. Particular weight will be given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination in Arts did not obtain 30 per cent. of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of those languages will involve the loss of the examination.

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the first period of the course of medical studies. The subjects for this examination are Anatomy, Physiology, and Materia Medica (Pharmacology).

The Third Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of medical studies. The subjects for this examination will be Anatomy and Physiology.

The Examination for the Primary Medical Degrees.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the fourth year. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology; Mental Diseases; Medical Jurisprudence; and Hygiene. (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology. (*c*) Midwifery and Gynæcology, with Diseases of Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions, the candidate will, in addition to the parchment diplomas recording his admission to the Primary Medical Degrees of M.B., B.Ch., and B.A.O., receive a certificate of having passed a qualifying examination in the subjects of Medicine, Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to the Primary Medical Degrees.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of three academical years from the time of obtaining the degree of M.B. Provided, however, that all persons who were students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to be admitted to the degree of M.D., instead of the degree of M.B., upon passing the examination herein prescribed for the M.B. degree. Every candidate will be examined at the bedside, and required to diagnose at least six cases, medical and surgical, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners, and to discuss all the questions arising thereon. Every candidate is required to submit to the medical examiners, for their approval, a thesis certified by him (or her) to have been composed by himself (or herself). No thesis will be approved which does not contain some original or personal observations in practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

The M.Ch. Degree.—This degree will be conferred only on graduates in Medicine of the University. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination on Surgical Instruments and Appliances; (*d*) an examination in Operative Surgery.

The Mastership in Obstetrics.—This degree will be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children, and the use of instruments and appliances; and will include—

Digitized by Google

(*a*) a written examination; (*b*) a clinical examination as far as practicable; (*c*) an oral examination, with practical illustrations; (*d*) an examination on Instruments and Appliances.

The Diploma in Sanitary Science.—This diploma will be conferred only on graduates in Medicine of the University. The examination will include the following subjects:—Physics, Climatology, Chemistry, Geology, Sanitary Engineering, Hygiene, Sanitary Law, and Vital Statistics. Proficiency in practical work and an adequate acquaintance with the instruments and methods of research which may be employed for Hygienic investigations are indispensable conditions of passing the examination.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Local Government Board as a qualification in Surgery as well as in Medicine.[12]

Regulations.—Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in a manner prescribed by the General Medical Council. Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—1. Attending the practice of a hospital or other institution recognised by the College for that purpose; 2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery; 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals.[13] Of having discharged the duties of a medical Clinical Clerk during six months, and of a Surgical Dresser during other six months; and of having been engaged during six months in the Clinical Study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. Of having passed the professional examinations, of which there are three, each partly written, partly oral, and partly practical. The subjects of the first examination are: Chemistry, including Chemical Physics—viz., Heat, Light, and Electricity; Materia Medica and Pharmacy; and Osteology. The subjects of the second examination are Anatomy and Physiology. The subjects of the final examination are: Medical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Medicine; Surgical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Surgery; Midwifery and Diseases peculiar to Women; Forensic Medicine; Public Health and Therapeutics.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland, or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

[12] Candidates for the Licence of this College who shall have commenced professional study on or after Oct. 1st, 1884, are required to comply with the Regulations of an Examining Board for England formed by the Royal College of Physicians of London and the Royal College of Surgeons of England. These Regulations may be obtained on applying to F. G. Hallett, Esq., Secretary, Examination Hall, Victoria Embankment, W.C.

[13] A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The diploma of Member of this College is not now granted apart from the licence of the Royal College of Physicians except to students who commenced their professional studies prior to Oct. 1st, 1884. It does not seem necessary, therefore, to reproduce the regulations of the College at the present date. Students of such standing as to be subject to them may consult our second volume for last year, where they will be found fully set out on pages 474 and 475. Students of a later date will be subject to the regulations issued by the Joint Examining Board of the two Royal Colleges of Physicians and Surgeons.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after the 1st of October, 1884.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to comply with the following regulations, and to pass the examinations hereinafter set forth. Every such candidate who shall commence professional study on or after Oct. 1st, 1884, will be required, at the times prescribed for the respective examinations, to produce satisfactory evidence—1. Of having been registered as a medical student by the General Medical Council. 2 Of having been engaged in professional studies at least forty-five months, during which not less than three winter sessions and two summer sessions shall have been passed at one or more of the medical schools recognised by the two Colleges. 3. Of having received instruction in the following subjects: (*a*) Chemistry, including Chemical Physics; (*b*) Practical Chemistry; (*c*) Materia Medica; (*d*) Pharmacy. 4. Of having performed Dissections at a recognised medical school during not less than twelve months. 5. Of having attended at a recognised medical school—(*a*) a course of lectures on Anatomy during not less than six months, or one winter session; (*b*) a course of lectures on General Anatomy and Physiology during not less than six months, or one winter session; (*c*) a separate practical course of General Anatomy and Physiology during not less than three months. 6. Of having attended at a recognised medical school—(*a*) a course of lectures on Medicine during not less than six months, or one winter session; (*b*) a course of lectures on Surgery during not less than six months, or one winter session; (*c*) a course of lectures on Midwifery and Diseases peculiar to Women during not less than three months; (*d*) systematic practical instruction in Medicine, Surgery, and Midwifery; (*e*) a course of lectures on Pathological Anatomy during not less than three months; (*f*) demonstrations in the post-mortem room during the whole period of attendance on clinical lectures; (*g*) a course of lectures on Forensic Medicine during not less than three months. 7. Of having attended, at a recognised hospital or hospitals, the practice of Medicine and Surgery during three winter and two summer sessions. 8. Of having attended at a recognised hospital or hospitals during nine

Digitized by Google

months' Clinical Lectures on Medicine, and during nine months' Clinical Lectures on Surgery, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. 9. Of having discharged, after he has passed the Second Examination, the duties of a Medical Clinical Clerk during six months, and of a Surgical Dresser during other six months. 10. Of having performed operations on the dead subject to the satisfaction of his teacher. 11. Of having received instruction in the practice of Vaccination.

Professional Examinations.—There are three Professional Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, Secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry, Chemical Physics, Materia Medica, Pharmacy, Elementary Anatomy, and Elementary Physiology. A candidate may take this examination in three parts at different times, or he may present himself for the whole at one time. A candidate will be admitted to the examination on Chemistry and Chemical Physics, Materia Medica, and Pharmacy, on producing evidence of having been registered as a medical student by the General Medical Council, and of having received instruction in Chemistry, Materia Medica, and Pharmacy; or he may take Materia Medica and Pharmacy as part of the Second Examination; but he will not be admitted to the examination on Elementary Anatomy and Elementary Physiology earlier than the end of his first winter session at a medical school, or than the completion of his first six months' attendance at a recognised Medical School during the ordinary sessions—i.e., exclusive of the months of April, August, and September. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of the first and second parts of this examination conducted at a University in the United Kingdom, in India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the First Examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the parts, £3 3*s.*

The subjects of the Second Examination are Anatomy and Physiology. A candidate is required to present himself for examination in Anatomy and Physiology together until he has reached the required standard to pass in one or other of these subjects; but no candidate will be allowed to pass in one of the subjects without obtaining at the same time at least half the number of marks required to pass in the other subject. A candidate will be admitted to the Second Examination after the lapse of not less than six months from the date of his passing the First Examination, on producing evidence of having completed, subsequently to registration as a medical student, eighteen months of professional study at a recognised medical school or schools, and of having complied with the regulations prescribed in Section I., Clauses 4 and 5. A candidate rejected in either part or in both parts of the Second Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the Second Examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the two parts, £3 3*s.*

The subjects of the Final Examination are: Medicine, including Therapeutics, Medical Anatomy, and Pathology; Surgery, including Surgical Anatomy and Pathology; Midwifery and Diseases peculiar to Women. A candidate may present himself for examination in these three subjects or parts separately or at one time. A candidate will be admitted to the Third or Final Examination on producing evidence—(1) of being twenty-one years of age; (2) of having passed the Second Examination; and (3) of having studied Medicine, Surgery, and Midwifery, in accordance with the regulations prescribed in Section I., Clauses 2 and 6 to 10. The Colleges do not admit to either part of the Third or Final Examination any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months, nor till the expiration of two years after his having passed the Second Examination. A candidate rejected in the Third or Final Examination, or in one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than six months from the date of rejection, and he will be re-examined in the subject or subjects in which he previously failed to pass. Any candidate who shall have obtained a colonial, Indian, or foreign qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and examination equivalent to those required by the Regulations of the two Colleges, shall, on production of satisfactory evidence as to age and proficiency in Vaccination, be admissible to the Second and Third Examinations.

The fees for admission to the Third or Final Examination are as follows: for the whole examination, £15 15*s.*; for re-examination after rejection in Medicine, £5 5*s.*; for re-examination after rejection in Surgery, £5 5*s.*; for re-examination after rejection in Midwifery, £3 3*s.*

Notice.—A candidate referred at the Second Examination in either or both subjects is required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teacher, or teachers, in a recognised place of study, his Anatomical and Physiological Studies, or his Anatomical or Physiological Studies, as the case may be, during a period of not less than three months subsequently to the date of his reference.

A candidate referred on the Third or Final Examination, or on one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, at a recognised hospital during the period of his reference; and, in regard to Midwifery, a certificate of having received, subsequently to the date of his reference, not less than three months' practical instruction in that subject by a recognised teacher.

Any candidate who withdraws from a part or parts of an examination for which he has sent in his name will not be admissible to such part or parts until the expiration of six months, without the special permission of the Committee of Management.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three co-operating bodies.

The three co-operating bodies grant their single qualifications only to candidates who already possess another and opposite qualification in Medicine or Surgery, as the case may be. Copies of the Regulations for the single qualification of any of the bodies may be had on application to the respective secretaries.

Professional Education.—1. Candidates must have been engaged in professional study during forty-five months from the date of registration as medical students by the General Medical Council, which period shall include not less than four winter sessions' attendance at a recognised medical school. 2. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Anatomy, one course, during at least six months; Practical Anatomy, twelve months; Chemistry, one course, six months; Practical or Analytical Chemistry, one course, three months; Materia Medica, one course, three months; Physiology, one

Digitized by Google

course, six months; Practice of Medicine, one course, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, one course, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, one course, three months; Medical Jurisprudence, one course, three months; Pathological Anatomy, one course, three months. The six months' courses delivered in Scotland must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than 50 lectures. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 3. The candidate must also produce the following certificates:—(*a*) Of having attended not less than six cases of labour, three of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. It is, however, strongly recommended that, where opportunity is given, the candidate should either attend for three months the in-door practice of a lying-in hospital, or attend personally not less than twenty cases of labour, and that at least the first six of these cases should be attended under the direct supervision of the practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the Medical and Surgical practice of a public general hospital containing on an average at least eighty patients, and possessing distinct staffs of physicians and surgeons. (*d*) Of having attended for six months (or three months, with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the co-operating authorities; or the out-patient practice of a recognised general hospital, or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the co-operating authorities; this attendance should be made after the student has passed the First and Second Examinations. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination, and of having performed operations under the teacher's inspection during a period of not less than six weeks.

Candidates will be subjected to three Professional Examinations, herein called the First Examination, the Second Examination, and the Final Examination, to be conducted at separate times, partly in writing and partly practically and orally.

First Examination.—The First Examination will embrace Chemistry,[14] Elementary Anatomy,[15] and Histology,[16] and will take place not sooner than the end of the first year, including the period of a winter and a summer session. The sum of £5 5*s.* must be paid to the inspector of certificates for this examination, not later than 4 P.M. of the Friday preceding it, after which no candidate will be entered. In the case of a candidate being unsuccessful at this examination, he will be readmitted to examination after a prescribed interval on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has gained an absolute pass in one or more subjects at this board. This rule will also apply to any subsequent rejection. Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the first examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects.

[14] The examination in Chemistry will embrace the following particulars: Chemical Physics (meaning thereby Heat, Light, and Electricity); the principal Non-Metallic and Metallic Elements, and their more common combinations; also the leading Alcohols, Organic Acids, Ethers, Carbohydrates, and Alkaloids. The candidate will also be examined practically in Testing.

[15] Elementary Anatomy will embrace: Anatomy of the Bones and Joints of the whole body, and of the Muscles, chief Bloodvessels, and Nerves of the Upper and Lower Extremities.

[16] Histology will be held to include a knowledge and recognition of the morphological elements and structure of Skin, Bone Cartilage, Fibrous Tissue, Hair, Nails, Teeth, Blood, Muscle, Nervous Tissue, and the appearance and distribution of all the different forms of Epithelium, along with a general knowledge of the properties of cells. The examination of the subject will be oral and practical.

Second Examination.—The Second Examination will embrace Anatomy, Physiology, Materia Medica and Pharmacy, and will not take place before the termination of the summer session of the second year of study, including two winters and two summers. The sum of £5 5*s.* must be paid to the inspector of certificates for this examination, not later than one week before the day of examination, after which no candidate will be entered. In case of failure, the candidate will be readmitted to examination after the expiry of the prescribed period, on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has obtained credit at this board for one or more subjects. Any candidate who shall produce satisfactory evidence of having passed in any of the subjects of the second examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects; but no examination before such boards will be recognised as giving exemption unless it is coextensive in its scope with the equivalent examination of this board, and is the only or the final examination on the subject or subjects required by the board at which it was passed. When the candidate has not paid the fee of the first examination to this board, his fee payable in respect of the second examination shall be £10 10*s.*

Final Examination.—The Final Examination will embrace the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy, and Pathology); Clinical Medicine; the Principles and Practice of Surgery (including Surgical Anatomy and Surgical Pathology); Clinical Surgery; Midwifery and Gynæcology; Medical Jurisprudence; and Hygiene; and shall not take place before the termination of the full period of study. The fee payable for this examination, which in the case of candidates who have passed the First and Second Examinations will be £15 15*s.*, must be paid to the inspector at Edinburgh or Glasgow, as the case may be, not later than one week prior to the examination day, after which no candidate will be entered. In case of a candidate being unsuccessful at this examination, £10 10*s.* shall be returned to him, the remaining £5 5*s.* being retained to meet the expense of conducting the examination. This rule will also apply to any subsequent rejection. Any candidate admitted to the Final Examination, on the footing of having passed in the subjects of the First and Second Examinations at a recognised board, shall, on entering, pay the full fee of £26 5*s.*; and in the event of his being unsuccessful, £15 15*s.* will be returned to him at his first and £21 at every subsequent rejection. Candidates will not be exempted from examination in any of the subjects of the Final Examination, though some of them may have formed part of Examinations passed before other boards.

Any Graduate in Medicine of a British or Irish University, and any Graduate or Licentiate in Medicine of any recognised Universities and Colleges in India and the British Colonies, who has passed at his University such an examination or examinations as comprise the subjects of the First and Second Examinations of this Board, and who has completed not less than four years' Medical Study, including all the subjects of the curriculum, is admissible to the Final Examination. Any candidate so admitted shall pay a fee of twenty-five guineas at the time of entering for the examination. The sum of £20 will be returned to unsuccessful candidates.

There are six periods of examination annually, four in Edinburgh and five in Glasgow, and candidates may present themselves at either examining centre irrespective of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, 1, George-square; and the Registrar in Glasgow, Mr. A. Duncan, 242, St. Vincent-street, to whom fees and certificates must be sent.

KING AND QUEEN'S COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Two sets of regulations are at present in force, under which examinations take place for the conjoint diploma of these bodies. The older regulations, under which students who commenced their studies before Oct. 1st, 1889, may be examined, have appeared in our Students' Number in previous years, and will be found on pp. 477 and 478 of our second volume for last year. The following regulations are obligatory on all students commencing on or after the date already mentioned:—

Digitized by Google

PRELIMINARY EXAMINATION AND REGISTRATION.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence—(*a*) of having, before entering on medical studies, passed a Preliminary Examination in general education recognised by the General Medical Council; and (*b*) of having been registered by that Council as a Student in Medicine. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of twenty-one years.

Preliminary Examination.—The subjects of examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration, except that it includes the additional subject Physics, which may be passed at the Preliminary Examination or at a subsequent Supplemental Examination, at an extra fee of £1 1*s*. In no case can Physics be deferred to the First Professional Examination.

PROFESSIONAL EXAMINATIONS.

Every candidate is required to pass four Professional Examinations, one at the end of each year of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body. All examinations shall be conducted as far as possible by demonstration of objects placed before the candidates.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination, including Physics; (2) of having been registered as a medical student by the General Medical Council; and (3) of having attended in winter a course of (*a*) lectures on Practical Anatomy, (*b*) Demonstrations and Dissections, and (*c*) lectures on Theoretical Chemistry, (*d*) Practical Chemistry, three months' summer course, (*e*) Practical Pharmacy—(1) evidence of attendance for three months in the Compounding Department of a Clinical Hospital, which hospital shall have satisfied the Committee of Management that its means of instruction are sufficient, and shall return to the Committee the names of its students at the commencement of the course, together with a record of their attendance at its close; or (2) evidence of attendance on a course of Practical Pharmacy in a recognised Medical School, the course to consist of not less than twenty demonstrations; or (3) evidence of having served a full apprenticeship of three years, or of having acted as paid assistant for not less than one year in the establishment of a Licentiate Apothecary or of a registered Pharmaceutical Chemist.[17] The fee for this examination is £15 15*s*. The subjects of the First Professional Examination are the following:—1. Chemistry: Elementary Chemistry—Inorganic and Organic, as found in Roscoe's Lessons on Elementary Chemistry,—with a practical examination in the Laboratory. 2. Anatomy: Bones, with attachments of Muscles and Ligaments—Joints. 3. Pharmacy: Practical Pharmacy, Dispensing of Drugs, Methods of Administration of Medicines, Reading of Prescriptions.

Second Professional Examination.—Every candidate is required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination; also certificates of having, in his second or a later year of professional study, attended—(1) A Medico-Chirurgical Hospital for nine months, together with evidence of having taken notes to the satisfaction of the physicians or surgeons in charge of the cases, and certified under their hands, of at least three Medical cases and three Surgical cases, in the wards of a recognised Medico-Chirurgical Hospital. (2) Courses of Lectures as follow:—Winter courses: Practical Anatomy; Demonstrations and Dissections. Summer courses (three months): Histology; Materia Medica. The fee for this examination is £10 10*s*. The subjects of the Second Professional Examination are the following—1. Anatomy: The Anatomy of the whole Human Body. 2. Histology. 3. Hospital Practice: Methods of Physical Diagnosis; Application of Urinary Tests; General Principles of the Treatment of Fractures, of Dislocations, of Wounds, and of Hæmorrhages; Bandaging; General Principles of Case-taking. 4. Physiology: Circulation; Respiration; Digestion. 5. Materia Medica. Candidates are examined on three separate days.

Third Professional Examination.—Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination; also certificates of having in his third, or a later, year of professional study attended—(1) A Medico-Chirurgical Hospital for nine months, or acted for six months as resident pupil, together with evidence of having taken notes to the satisfaction of the physicians and surgeons in charge of the cases, and certified under their hands, of at least three Medical cases and three Surgical cases in the wards of a recognised Medico-Chirurgical Hospital. (2) Courses of Lectures as follow:—Winter courses: Demonstrations and Dissections; Medicine; Surgery; Physiology. Summer course (three months): Medical Jurisprudence. The fee for this examination is £9 9*s*. The subjects for the Third Professional Examination are the following—1. Anatomy; Surgical Anatomy. 2. Surgery: Surgery as in the Second Professional Examination; also Inflammation, with its varieties and consequences; Fractures; Dislocations; Injuries, mechanical, chemical, physical—their immediate and remote effects; Hernia; Surgical Diseases of Bloodvessels; Diseases of Bones; Diseases of Joints; Pyæmia; Septicæmia. 3. Medicine: Medicine as in the Second Professional Examination; also Diseases of the Heart and Circulatory System, of the Respiratory Apparatus, of the Abdominal Cavity, of the Skin; the Exanthemata; and the Continued Fevers. 4. Physiology.

Fourth or Final Professional Examination.—Every candidate is required, before admission to the Final Examination, to produce evidence—(1) of having passed the Third Professional Examination; (2) of having in his fourth or a later year of professional study (*a*) attended a Medico-Chirurgical Hospital for nine months as extern pupil, or acted for six months as resident pupil, unless a certificate to that effect has been accepted in the third year; (*b*)[18] a winter course of lectures on Midwifery. Certificates will also be required—(1) Of having attended a recognised midwifery hospital or maternity for six months in the winter or summer of the fourth year, with evidence of having been present at thirty labours. (2) Of having for not less than three months, in either the third or fourth year, studied fever in a recognised clinical hospital containing fever wards, and recorded from daily personal observation at least five cases of fever to the satisfaction of the attending clinical physician, as attested by his signature. For the purposes of this regulation the word "fever" is held to include the following diseases only—viz., typhus, typhoid or enteric fever, scarlet fever, small-pox, and measles. (3) Of having attended a course of Operative Surgery in the summer session of either the third or the fourth year. (4) Of having attended, at a recognised ophthalmic and aural hospital, or at a recognised ophthalmic and aural department of a general hospital, clinical lectures on Ophthalmic and Aural Surgery during a period of three months. The fee for this examination is £6 6*s*. The subjects for the Fourth or Final Examination are the following—1. Medicine. 2. Surgery. 3. Therapeutics. 4. Pathology. 5. Midwifery and Diseases peculiar to Women. 6. Forensic Medicine in reference to Medicine, Surgery, and Midwifery; Hygiene. 7. Ophthalmic and Aural Surgery.[19] Candidates may present themselves for examination in *all* the subjects of the Final Examination at the *same* term; or, at one term, in Medicine, including Therapeutics and Pathology, and Clinical Medicine; at a second term, in Surgery, including Therapeutics and Pathology, Ophthalmic and Aural Surgery, Clinical Surgery, and Operations; at a third term, Midwifery, Gynæcology, Forensic Medicine, and Hygiene. Candidates must pay the full fee before being admitted to any part of the examination. Candidates may take the groups in any order they please. No candidate will receive any diploma till the entire examination is completed.

[17] Licentiate Apothecaries and Licentiates of the Pharmaceutical Societies of Great Britain and Ireland are exempt from attendance on Practical Pharmacy.

[18] On and after July 1st, 1891, a certificate of having attended a course of lectures on Pathology will be required in addition to the above-named lectures.

[19] Students who commenced study before July, 1879, are exempt from both the certificate for study and the special Ophthalmic Examination, but are liable to be examined by the surgical examiners in Ophthalmic Surgery. Those who commenced before February, 1882, are exempt from the special examination, on producing the certificate of three months clinical ophthalmology required before that date. Those who commenced after February, 1882, must pass the special examination.

REJECTIONS AND RE-EXAMINATIONS.

Candidates at the First, Second, and Third Professional Examinations get credit for each subject in which they pass. In any subject in which they fail to pass they are "referred."

Immediate re-examination.—Candidates who pass in all subjects but one at the First, Second, or Third Professional Examination may, with the consent of the examiners in that subject, be re-examined in the same, if the Court of Examiners consider them deserving. The Court of Examiners decide at their conference whether or not a re-examination is to be granted, and if granted, it will be held as soon as may be before the Term Examination is concluded.

Subsequent re-examination.—Candidates who have been referred must present themselves at a subsequent examination in the subjects in which they have failed, but must satisfy the examiners in the same before proceeding to the examination of the year.

In the case of candidates so referred, the examiners are authorised to consider for what period, and in what subjects, each candidate is to be referred back to his studies, and to make a recommendation accordingly to the Committee of Management, who may authorise the re-examination of the candidate at such examination as they may think fit. The examiners are also empowered to recommend to the Committee of Management, in the case of candidates so referred, whether or not they should be allowed to continue attendance on lectures and obtain certificates as required for the next Professional Examination.

EXEMPTION OF CANDIDATES UNDER THIS SCHEME.

The following exemptions have been agreed to by the committee:—Primary Examination, Royal College of Surgeons, England, exempts from First, Second, and Third Examinations of Conjoint Scheme. Second Medical Examination, Royal University of Ireland, exempts from First Examination of Conjoint Scheme, with the exception of an examination in Pharmacy. M.B. Examination, Royal University of Ireland, exempts from First, Second, and Third Examinations of Conjoint Scheme. First Examination, English Conjoint Examining Board, exempts from First and Second Examinations of Irish Conjoint Scheme. Second Examination, English Conjoint Examining Board, exempts from First, Second, and Third Examinations of Irish Conjoint Scheme. First and Second Examinations, Scotch Conjoint Scheme, exempts from First and Second Examinations of Irish Conjoint Scheme. Primary Examination, Physicians and Surgeons of Glasgow, exempts from First and Second Examinations of Irish Conjoint Scheme. First and Second Examinations of Apothecaries' Society, London, exempts from First and Second Examinations of Irish Conjoint Scheme. The Intermediate Examination of the Victoria University, Manchester, exempts from the First and Second Examinations of Irish Conjoint Scheme. Provided that in each case the candidate shall have complied with the regulations laid down under this Conjoint Scheme for the examination at which he is about to present himself. No exemptions are made in respect of portions of examinations passed under other licensing bodies.

EXEMPTIONS OF CANDIDATES UNDER FORMER SCHEMES.

I. (*a*) Candidates who have passed the First Professional Examination, as hitherto conducted by the College of Surgeons, may present themselves for the Second Professional Examination under the Conjoint Scheme; (*b*) candidates who have passed the Second Professional Examination of the College of Surgeons may present themselves for the Third Examination under the Conjoint Scheme; (*c*) candidates who have passed the Third Professional Examination of the College of Surgeons may present themselves for the Fourth or Final Examination under the Conjoint Scheme. Provided that in each case the candidate shall have complied with the regulations laid down under the Conjoint Scheme for the examination at which he is about to present himself. But in the case of students registered as such prior to June 1st, 1887, the Committee of Inspection shall have power to vary the regulations when special circumstances shall appear to warrant it.

II. Candidates who have passed the first half of the Professional Examination at the College of Physicians or at the College of Surgeons under the old scheme may present themselves for the Final Examination under the Conjoint Scheme, provided they have complied with the regulations under the Conjoint Scheme for that examination.

III. The Committee of Inspection shall have power to exempt from certain examinations under the Conjoint Scheme candidates who previously to July 1st, 1887, would be exempt from equivalent examinations at the College of Physicians or College of Surgeons, under the Regulations of the Colleges as existing prior to the operation of the Conjoint Examination Scheme. Provided that in each case the candidate shall have complied with the regulations laid down under this Conjoint Scheme for the examination at which he is about to present himself.

SOCIETY OF APOTHECARIES OF LONDON.

Every student purposing to study Medicine must previously pass a Preliminary Examination in Arts qualifying for registration as medical student. Such examination is held quarterly in the Hall of the Society on the first Friday and following day in March, June, September, and December, and is conducted by means of printed papers. Candidates will be examined in English, Latin, Mathematics, Elementary Mechanics, and one of the following subjects at the option of the candidate: Greek, French, German, Logic, Botany, and Elementary Chemistry. The subjects may be passed at one or more examinations, and no subject in which a candidate has passed before any examining body recognised by the Medical Council can be taken up again except as a special subject. Notice must be given to the Secretary, and the fee of 1 guinea paid a fortnight prior to the day of examination. Medical study before registration as medical student is not recognised, with the exception of Chemistry, Materia Medica, Pharmacy, and Dispensing. Candidates can present themselves for examination in special subjects; the fee for each subject is 1 guinea. A pass-list is published and sent to every candidate.

The examinations to be passed for the Diploma in Medicine, Surgery, and Midwifery, which is registrable under the provisions of the Medical Act, 1886, are Primary and Final, all being written, oral, and practical. The Primary Examinations are held quarterly on the first Wednesday and on the Monday and Thursday of the same week in the months of January, April, July, and October. The Final Examinations are held monthly, and consist of—(1) the examination in Surgery on the second Wednesday and following days; (2) the examination in Medicine, on the third Wednesday and on the Monday and Thursday of the same week. The course of medical study must extend over four years, and not less than three winter and two summer sessions must be passed at a recognised hospital and school of medicine. Candidates intending to present themselves for examination must give fourteen days' notice. A form for the purpose will be sent on application. The fee must be forwarded at the same time, with all required certificates, to the Secretary. The fee for the examinations is £10 10*s.*, which in the event of failure is not returned. A fee of £3 3*s.* is required for every re-examination.

The course of study required to qualify for the Primary Examinations is as follows:—Lectures on Chemistry and Chemical Physics, not less than six months; Practical Chemistry in a laboratory, three months; Materia Medica, three months; Practical Pharmacy and Dispensing, three months, instruction in which must be given by a registered medical practitioner, or in a public hospital, infirmary, or dispensary. Evidence of having received instruction in these subjects before registration as medical student will be received. This first part of the Primary Examination may be passed at any period after registration. The second part includes Anatomy, Physiology and Histology, with an examination on the dissected body: to qualify for this the candidate must have received instruction in Anatomy, not less than six months; Practical Anatomy with Demonstrations, twelve months; Physiology, six months; Histology with Demonstrations, three months. Candidates will be excused any or all of the subjects of the Primary on producing evidence that they have passed equivalent examinations before an examining body recognised by the Medical Council

To qualify for the Final Examination the following course of study must be observed: Hospital Practice, Surgical and Medical, with Post-mortem Examinations, not less than three winter and two summer sessions. No hospital is recognised for this purpose which is not in connexion with an established medical school. Lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Surgical Dresser, three months; Lectures on the

Digitized by Google

Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Medical Clinical Clerk, three months; Forensic Medicine, Toxicology, Hygiene, and Insanity, three months; Lectures on Obstetric Medicine, including Gynæcology, three months; Clinical Instruction in the same, three months; a Course of Practical Midwifery; personally conducted Twenty Midwifery Cases. The offices of Dresser and Clinical Clerk may be discharged at a hospital, infirmary, or dispensary where sufficient opportunities are afforded for the acquirement of practical knowledge.

The above form the subjects of the Final Examination, which cannot be passed before the expiration of forty-five months after registration as medical student. There is no exemption from any portion of the Final Examination. The first part, besides the Principles and Practice of Surgery and an Examination of Surgical Cases, includes Surgical Pathology, Surgical Anatomy and Operative Manipulation, and Surgical Instruments and Appliances. The second part of the Final includes an Examination of Medical Cases, and, besides the subjects named, a Microscopic Examination of Morbid Structures and Obstetric Instruments and Appliances. Part II. may be taken before Part I. if desired. The following certificates must be produced prior to the Final Examination: 1. Certificate of birth. The candidate must be twenty-one. 2. Certificate of moral character. 3. Certificate of the Course of Medical Study, which must be signed by the Dean of the Medical School or other authority. A schedule for this purpose can be obtained at the Hall. 4. Certificate of having performed operations on the Dead Body. 5. Certificate of Proficiency in Vaccination, signed by a teacher recognised by the Local Government Board.

The Examination for a Certificate to act as an Assistant in Compounding and Dispensing Medicines is held on the third Thursday of every month, and will be as follows: In Translating Prescriptions; in the British Pharmacopœia; in Materia Medica and Botany; in Pharmacy and Pharmaceutic Chemistry. The fee is 2 guineas. A week's notice must be given.

Prizes.—A Gold Medal and a Silver Medal are given annually by the Society for proficiency in Materia Medica and Pharmaceutic Chemistry. All students, prior to the close of their third year of study, dating from registration, may compete, provided they have not been candidates before. The examination, which is written, oral, and practical, is held in the month of August. The required standard must be attained.

A Gold and a Silver Medal are also given for proficiency in Botany. The examination will take place in the month of June. Female candidates can compete.

Due notice of these examinations will be given in the medical journals.

Tickets of admission to the Lectures on Botany, given by J. G. Baker, Esq., F.R.S., F.L.S., of Kew, at the Society's Garden, at Chelsea, during the months of May, June, and July, can be had on application.

Attendance is given daily at the Hall of the Society, Blackfriars, E.C., from 10 to 4 o'clock, Saturdays excepted.

ROYAL COLLEGE OF SURGEONS, IRELAND, AND THE APOTHECARIES' HALL OF IRELAND.

Every candidate for the Conjoint Diplomas is required to pass a Preliminary Examination and four Professional Examinations.

First Professional Examination.—Candidates will be required, before admission to the First Professional Examination, to produce evidence—1. Of having been registered by the Medical Council as medical students at least nine months before examination. 2. Of having attended (*a*) Practical Anatomy, (*b*) Chemistry, (*c*) Demonstrations and Dissections, (*d*) Practical Chemistry, (*e*) Physics, (*f*) Practical Pharmacy for three months in the Compounding Department of a Clinical Hospital, or a School of Pharmacy, or in the Compounding Establishment of a Licentiate Apothecary. The fee for this examination is £12 12*s*. Candidates will be examined on Physics, Chemistry, and Anatomy (Osteology).

Second Professional Examination.—Candidates must produce evidence of having passed the First Professional Examination; also certificates of having subsequently attended—(*a*) a Medico-Chirurgical Hospital for nine months, and of having taken notes of at least three Medical cases and three Surgical cases, or a certificate of Clinical Clerkship; (*b*) the following courses of Lectures: (1) Demonstrations and Dissections; (2) Physiology; (3) Surgery, winter courses, six months; (4) Materia Medica; (5) Practical Physiology, including Histology, summer courses, three months. The fee for this examination is £7 7*s*. Candidates will be examined in Anatomy, Physiology, Materia Medica and Pharmacy.

Third Professional Examination.—Candidates must produce evidence of having passed the Second Professional Examination; also certificates of having subsequently attended—(*a*) a Medico-Chirurgical Hospital for six months as resident pupil, or for nine months as extern pupil, and, in the latter case, notes of at least three Medical and three Surgical cases, or of having acted as Clinical Clerk at any period; (*b*) the following courses of Lectures: (1) Demonstrations and Dissections; (2) Medicine; (3) Midwifery and Diseases peculiar to Women, in winter courses (may be deferred to the fourth year); (4) Pathology;[20] (5) Medical Jurisprudence, Forensic Medicine, and Hygiene, in summer course. The fee for this examination is £7 7*s*. Candidates will be examined in Anatomy, Surgery, Medicine, and Medical and Surgical Pathology.

Fourth Professional Examination.—The candidate must produce evidence—(1) of having been registered as a medical student by the Medical Council at least forty-five months previously; (2) of having passed the Third Professional Examination; (3) of having subsequently attended—(*a*) a Medico-Chirurgical Hospital for nine months as extern pupil, or six months as resident pupil; (*b*) Lectures on Midwifery, a winter course (unless taken in the third year); (*c*) a recognised Midwifery Hospital, or Maternity, for six months in the winter or summer of either the third or the fourth year, with evidence of having been present at thirty labours; (*d*) of three months' study of Fever in a Clinical Hospital containing fever wards, and of having taken notes of at least five cases of fever (attendance at a fever hospital will not be recognised if concurrent with that on Practical Midwifery); (*c*) Operative Surgery in the summer session of either the third or fourth year; (*f*) Clinical Lectures in Ophthalmic and Aural Surgery (three months) at a recognised Ophthalmic Hospital, or at an Ophthalmic Department of a General Hospital. The fee for this examination is £7 7*s*.

Candidates will be examined on Medicine, Therapeutics, Surgery, Midwifery and Diseases peculiar to Women, Ophthalmic and Aural Surgery, and Forensic Medicine and Hygiene.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Admission into the Army and Indian Medical Services is gained as the result of competitive examination. Candidates for both services must, before being admitted to examination, possess the double qualification to practise Medicine and Surgery, and be registered under the Medical Act, and must also furnish satisfactory certificates of moral character. Candidates for the Army must be between the ages of twenty-one and twenty-eight, in good health, and both parents of unmixed European blood; for the Indian Service, between twenty-two and twenty-eight, of sound bodily health, and natural-born subjects of Her Majesty. Both are examined as to physical fitness by a Board of Medical officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with especial reference to Materia Medica, and for the Indian service Hindustani. Although the results of the examination on voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the lists, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination, the successful candidates for both services are

[20] The certificate in Pathology will not be required until further notice.

Digitized by Google

sent to the Army Medical School at Netley as "surgeons on probation," with the rank of lieutenant and the daily pay of 8*s*., to go through a four months' course of special instruction in the duties required of them in the service. The staff of the school consists of four professors, all of them men of acknowledged ability and high standing in their special departments. The Professorship of Military Medicine is at present vacant. Surgeon-General Sir T. Longmore, Kt., C.B., is Professor of Military Surgery; Surgeon-Major J. L. Notter, M.D., of Military Hygiene; and Sir W. Aitken, F.R.S., of Pathology. To each of these an Army Medical Officer is attached as Assistant Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, during sieges, and on board troopships and transports, &c. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant Professors of Medicine and Surgery, and receive practical instruction in the mode of examining recruits. The surgeons on probation are provided with quarters, and are members of the excellent mess established at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session five prizes are awarded: the Herbert Prize of £20 to the surgeon on probation who has obtained the highest number of marks at the London and Netley examinations conjointly; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination on Hygiene at Netley, combined with those given for the answers to a special question set on the same subject; the Martin Memorial Gold Medal to the highest number of marks in the final examination on Military Medicine, with the addition of those gained for a special question connected with it; the Montefiore Gold Medal and £21, awarded in the same manner for Military Surgery; and the Montefiore Second Prize, consisting of works on Military Surgery, to the surgeon on probation who obtains the second highest numbers in this branch.

Surgeons are promoted to be Surgeons-Major on completing twelve years' full-pay service, of which three must have been abroad. Before being promoted they will be required to pass an examination intended to test their progress and proficiency in all those branches of knowledge which are essential to their continued efficiency as medical officers, which may be taken at any time between the fifth and tenth year of service. It will embrace the following subjects: *a*. Surgery, operative and practical, including field surgery and transport of sick and wounded. *b*. Medicine and Pathology, including practical pharmacy and modes of prescribing and administering remedial measures, food, drink, &c. *c*. Hygiene, within the limits treated of in "Parkes' Practical Hygiene." *d*. Duties of executive medical officers during peace and war at home and abroad, and at sea, as defined in the various codes of regulations issued for their guidance. Medical officers possessing the following qualifications will be exempted from examination in Medicine, Surgery, and Hygiene respectively: *a*. The degree of Doctor of Medicine or Master in Surgery of any University in Great Britain or Ireland granting such degrees under a higher standard of examination than that for M.B. or B.Ch.; or the Membership of any Royal College of Physicians or the Fellowship of any College or Faculty of Physicians or Surgeons of Great Britain or Ireland granted under similar conditions in regard to their respective Licentiates, will be accepted in lieu of an examination in Medicine and Surgery. *b*. The diploma in Hygiene and State Medicine, or any corresponding diploma of any University in Great Britain or Ireland, such diploma being granted after examination, will be accepted in lieu of an examination in this subject. A certificate will be required from a recognised teacher of Surgery in any medical school at home or abroad in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator. A report on any subject of a practical professional character to be selected by the officer himself, and certified to be his own composition, and in his own handwriting, will also be required.

The selection of Surgeons-Major for advancement to the grade of Brigade Surgeon is made on the grounds of ability and merit, in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential Reports. He must be physically fit for general service, and have the necessary qualifying foreign and Indian service under existing rules. He must, before he can be selected for promotion to the grade of Brigade Surgeon, establish before an examining board, appointed for the purpose by the Director-General, his efficiency in the following subjects:—*a*. Hospital organisation and administration in peace and war. *b*. The administration, interior economy, command, and discipline of the Medical Staff Corps and bearer columns. *c*. The relations of the medical to all other departments and corps of the army, as defined by the various Codes of Regulations in force. *d*. Recruiting and invaliding. *e*. The management of sick and wounded in war. *f*. Field medical organisation. *g*. The transport of the sick and wounded by land and sea. *h*. The medical and surgical equipment and hospital arrangements for an army corps. *i*. The duties and responsibilities of medical officers, quartermasters, and non-commissioned officers and men of the Medical Staff Corps in regard to the charge and supervision of stores and equipments, and the nursing, dieting, and general management of the sick. *k*. The sanitary duties of medical officers in charge of camps and hospitals in the field and at the base of operations. *l*. The sanitary inspection and equipment of hospital ships and troop transports, and all other sanitary duties in camps, garrisons, and quarters. *m*. The origin, progress, and best methods of dealing with outbreaks of epidemic disease among troops under any given circumstance. *n*. The most approved methods of securing the sick, and especially the wounded, against pyæmia, septicæmia, and all other forms of blood poisoning, and the management and treatment of such outbreaks when they occur. *o*. Questions on Operative Surgery and Practical Medicine will also form part of this examination. A medico-topographical report will be required of any district or country in which British troops have been, or are likely to be, actively employed, as well as a sketch of the medical arrangements suitable for an army corps operating in such a district or country, compiled by the officer, and certified to be his own composition and in his own handwriting.

Brigade Surgeons, to be eligible for selection as Deputy Surgeons-General, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Deputy Surgeon-General are placed on the retired list at the age of fifty-five, and those of that rank and Surgeons-General at the age of sixty.

The regulations above noted respecting the promotion of Surgeons and Surgeons-Major are equally applicable to the Indian Medical Service.

The Report of a Committee appointed to inquire into the pay, status, and conditions of service of the Medical Officers of the Army and Navy has just been presented to Parliament. It is not yet known to what extent the authorities may adopt the recommendations of the Committee, but we have little doubt that the examination of Surgeons-Major before promotion to the grade of Brigade Surgeon will be dispensed with. It is probable also that some modification may be adopted in the mode of conducting the examination for promotion from the rank of Surgeon to that of Surgeon-Major, and that the exemption from a portion of it on the grounds stated above may be abolished.

The conditions of admission into the Naval Medical Service are the same as those for the Army; but the candidate is also required to declare his readiness to engage for general service, and to proceed on duty abroad whenever required to do so. After having passed the competitive examination in London the successful candidate will receive a commission as surgeon in the Royal Navy, "and will undergo a course of practical instruction in Naval Hygiene at Haslar Hospital."

Surgeons are promoted to Staff Surgeons after twelve

Digitized by Google

years from date of entry, provided they pass the requisite examination; and Staff Surgeons to Fleet Surgeons after twenty years' service, if recommended by the Director-General. Deputy Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed, of which not less than two have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty, and other grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay, time on half-pay will be taken as equivalent to one-third service on full-pay.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service:—

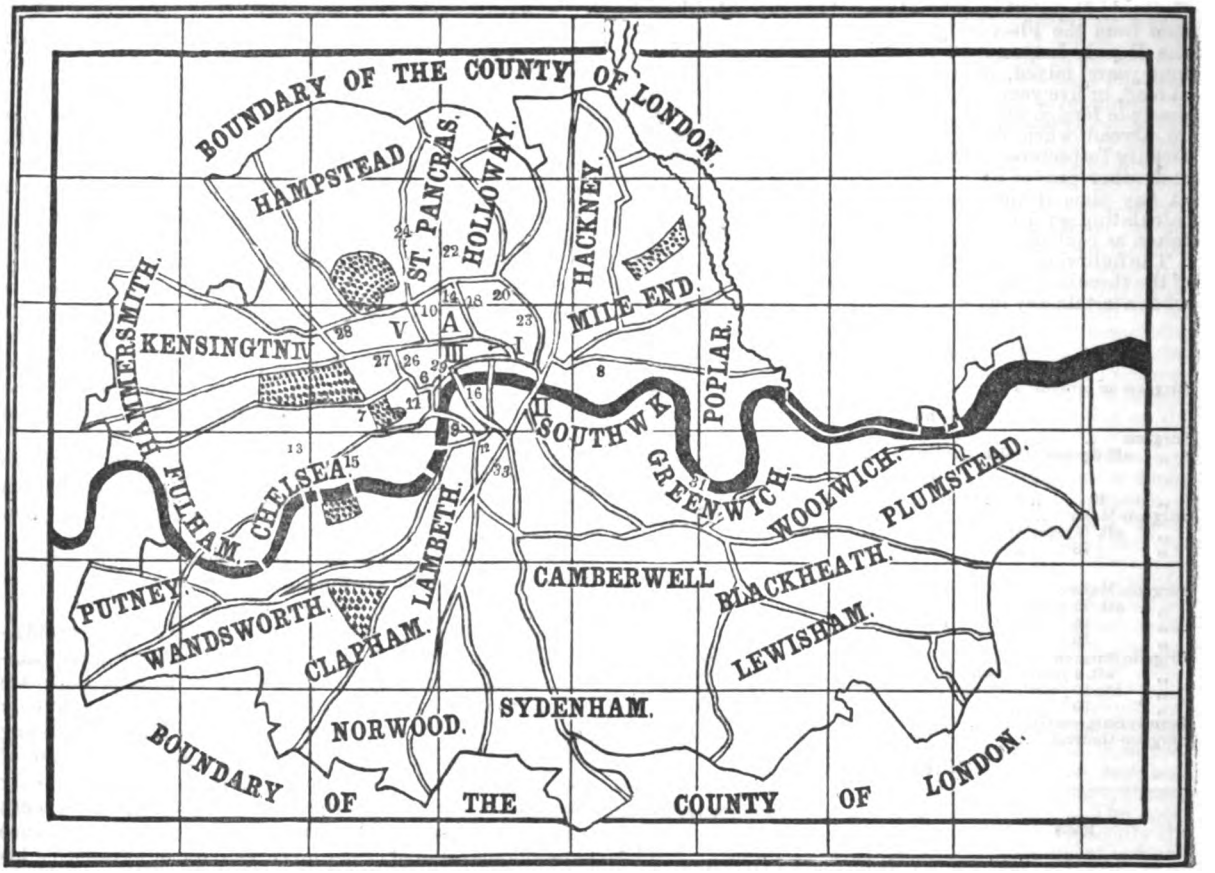
THE COST OF EQUIPPING A MEDICAL PRACTITIONER.

IN deciding upon the path to be selected for a lad whose calling in life is under consideration, the cost attending his due equipment for the profession or avocation of his choice is often a question of prime importance. It is, moreover, a question by no means easy to determine, especially in the case of the medical profession, and we have to-day presented our readers with the fullest materials available in the most perspicuous form. For this purpose we have produced, either by revision or compilation, the tables occupying pages 511 to 524 of the present impression, in which may be found collected in a comparatively small compass a large body of facts relating to this important topic. It will, however, be useful here to prefix a few remarks dealing with the subject in a general way, and adapted to aid the parent or intending student himself, as the case may be, to find his somewhat devious way through these voluminous details.

The cost of equipment, by which we mean the whole expense incidental to the education and legal qualification of a medical man may be conveniently distributed under three main heads:

1. Cost of maintenance.
2. Cost of education.
3. Cost of qualification.

Of these three items the first is by far the most considerable. It is, of course, quite true that a lad must be maintained somewhere, and it even happens in some fortunate cases that the student can live at home, and thus not only enjoy the comforts and amenities of home life while passing through his curriculum, but also minimise the expense of his support in the meantime. This, however, can only happen in a minority of cases. Commonly, the student must remove from home to take up a temporary residence at some educational centre for the purpose of prosecuting his studies, and then the present question assumes very important practical bearings.



To meet this case, arrangements have been made at some of the medical schools to provide board and lodging at cheap rates for a certain number of students. This is, of course, a part of the scheme of all the teaching universities, and it may be assumed that in the case of a student destined for one of these establishments the solution of this question will be well understood, and therefore present no difficulty. The difficulty does, however, arise in a very pronounced form in the case of students coming from the provinces to attend upon some one of the many London schools. To the illustration of this subject, therefore, we have devoted the map which accompanies this article. The London Schools of Medicine will be found indicated there in such a manner as to distinguish those which do afford residential facilities from those which do not; and, as the map is self-explanatory, it is perhaps unnecessary to refer more particularly at this point to its contents.

Dealing first, then, with the schools which do afford board and residence, it will be found that the rates charged vary within limits, which may be placed at £1 and £1 10*s.* a week. A mean between these figures may perhaps be taken to represent very fairly the bare cost of living in London to a young man in the position of a medical student of quiet habits and simple tastes.

The accommodation so provided is, however, very limited by comparison with the large number of men who are always pursuing medical studies in the metropolis. The great majority, therefore, must be received in private lodgings, and in such a case it may be a matter of considerable importance to find such accommodation in the near neighbourhood of the school at which a student proposes to attend. It will perhaps be useful for readers in the

MAP OF THE COUNTY OF LONDON, SHOWING MEDICAL SCHOOLS.

EXPLANATION.

I. *Medical Schools with a Complete Curriculum.*

A. With Residential Colleges.
- I. St. Bartholomew's Hospital.
- II. Guy's Hospital.
- III. King's College.
- IV. St. Mary's Hospital.
- V. Middlesex Hospital.

B. Without Residential Colleges.
- 6. Charing-cross Hospital.
- 7. St. George's Hospital.
- 8. London Hospital.
- 9. St. Thomas's Hospital.
- 10. University College Hospital.
- 11. Westminster Hospital.

II. *Ancillary Medical Schools affording instruction in particular subjects, &c.*
- 12. Bethlem Hospital.
- 13. Brompton Hospital for Consumption.
- 14. Central London Throat and Ear Hospital.
- 15. Hospital for Women, Chelsea.
- 16. Royal Hospital for Children and Women.
- 17. Hospital for Women (included in Group A).
- 18. Mr. Thomas Cooke's School.
- 19. Dental Hospital of London (included in Group A).
- 20. Royal Hospital for Diseases of the Chest.
- 21. Royal Ear Hospital (included in Group A).
- 22. Great Northern Central Hospital.
- 23. Royal London Ophthalmic Hospital.
- 24. London Temperance Hospital.
- 25. National Hospital for Paralysed and Epileptic (included in Group A).
- 26. Normal School of Science.
- 27. Royal Orthopædic Hospital.
- 28. Queen Charlotte's Hospital.
- 29. St. Peter's Hospital for Stone.
- 30. School of Pharmacy (included in Group A).
- 31. Seamen's Hospital.
- 32. Hospital for Sick Children (included in Group A).
- 33. South London School of Pharmacy.
- 34. College of State Medicine (included in Group A).
- 35. Royal Westminster Ophthalmic Hospital.

country to glance at our map for the purpose of realising how large a place London is. The map represents the newly constituted County of London—that is to say, the area commonly known as "London and suburbs." The scale of the map is a little larger than three miles to the inch; that is to say, the lines by which it is divided represent distances of two miles and cut it up into four-mile areas. It will readily be perceived, therefore, that it is quite possible without going out of London to be at a considerable distance from any one of the London schools. It should be borne in mind in this connexion that between many parts of the metropolis the means of communication are singularly deficient. Thus in going across London—as, for example, from east to west, or from north to south—the traveller will find no convenient railway communication. His most expeditious way of performing the journey will probably involve much deviation from the straight course, and many changes of vehicle if he confines himself to public conveyances, so that in point of fact he will occupy as long in going, for example, from Hampstead to Lewisham, or from Poplar to Kensington, as it would take to get from King's-cross to Peterborough, or from Paddington to Reading.

Happily, almost all this large area is covered by residential neighbourhoods, and there would be no actual difficulty about securing suitable accommodation within easy distance of any one of the medical schools.

Speaking very roughly, it may be said that the cost of bachelor lodgings with a respectable family ranges at about from 25*s.* to 30*s.* a week. A great many medical men are prepared to make homes for medical students, and such an arrangement presents obvious advantages to a young man

Digitized by Google

who is zealously affected in the cause of his studies. The cost is, in these circumstances, rather heavier, of course, but an addition of 10s. a week might fairly be expected to cover it in an ordinary case. A plan that London students often adopt, and sometimes with very happy results, is to share rooms with one another—two students, for instance, occupying one sitting-room. The saving is considerable, and if the society is congenial the advantages of company are superadded.

So much may suffice upon this first head—unless, indeed, we add, what probably the reader already understands, that the educational course extends practically over a period of four years. It is over such a period, therefore, that the student must be maintained.

As to the cost of education—that is to say, of the college course—it will obviously vary with the school selected and the studies pursued. The schools enumerated in our Class Guide on pp. 511–518 provide every one of them a more or less complete curriculum, and it will be seen that the fees payable vary very considerably. It will, however, be found that these variations are more matters of appearance than of reality. In the case, for example, of the Universities the charges are individually light, but they form items in a more comprehensive scheme of education, and in the case of some provincial schools the curriculum is better adapted to a part of the students' course than to the whole of it. Allowance must of course be made for such points as these; and then it will be found that, after all, the cost at various schools is not very materially different, and that it is fairly represented by a sum not greatly exceeding in the aggregate a hundred guineas. In reference to this matter, however, it is of very little use to generalise. The whole question is one of detail, and can only be adequately illustrated by a tabular statement, to which accordingly our readers may best refer.

In addition to the cost of the education properly so called, there is the item, too easily lost sight of in a general survey, of examination fees, which, though not in any case very considerable in amount, should be taken into consideration if precision is desired. These fees also vary, as a matter of course, with the various qualifications sought, and they are collected in the second of our tabulated statements, which occupies p. 519. This, again, is a matter of detail which no disquisition can make plainer than it appears in the tabular statement.

Having fairly considered these three heads of expense, the intending student or his guardian will be in a position to arrive at a safe judgment upon the all-important questions whether he can afford the outlay incidental to a medical education, and if so how the money is to be found.

When he has thus faced the worst he may turn to what will be the more attractive consideration of the very liberal pecuniary aids to medical study which are set out in some detail in the third of our tabulated statements, which occupies pp. 519–524. This is by no means an exhaustive list of scholarships maintained in support of medical education, and it may even be feared that it is not in all details quite accurate. The labour of compiling it from the heterogeneous and often inadequate materials which we have had at command has been considerable, and the difficulty of guarding against all the numerous possibilities of error has been proportionately great. We trust that our readers will bear this fact in mind, and, while making due use of the facilities of reference which such a table is adapted to afford, that they will be at the pains to verify any details culled from this collection of which they may intend to make use. The probability of securing some one or another of these many prizes may be quite reasonably taken into account in the case of an exceptionally clever lad, especially if his career at school has been marked by distinction. But it is hardly necessary to add a word of warning that "the best laid schemes of mice and men gang aft agley": and the only way of being secure is to have laid one's account with the worst that can happen.

METROPOLITAN MEDICAL SCHOOLS HAVING A COMPLETE CURRICULUM.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE. — The clinical practice of the hospital comprises a service of 750 beds, of which 676 are in the hospital at Smithfield, and 75 are for convalescent patients at Swanley.

Eight house physicians, ten house surgeons, and a midwifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. Two qualified assistant electricians are appointed every three months. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Forty ward dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes.—Two Lewis Open Scholarships in Science of the value of £65 each, tenable for one year, will be competed for in September. Candidates must not be more than twenty-five years of age, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics and Chemistry for one, Physiology and Biology for the other.—Two Junior Open Scholarships in the subjects of the Preliminary Scientific Examination of the London University will be competed for at the same time. Candidates must be under twenty years of age, and must become regular students.—The Jeaffreson Exhibition, of the value of £20, is awarded at entrance after examination in the subjects of general education. It is now an Open Exhibition.—A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry.—Kirke's Scholarship and Gold Medal in Clinical Medicine, value 40 guineas.—Lawrence Scholarship and Gold Medal, of the value of 40 guineas (founded in 1873 by the family of the late Sir William Lawrence). — Two Brackenbury Scholarships in Medicine and Surgery, £30 each.—Four Junior Scholarships in the subjects of study of the first year: 1st, £40; 2nd, £30; 3rd, £20; 4th, £10.

A prize of £15 for Anatomy has been founded by the late Mr. Henry Skynner in memory of his brother; a Scholarship of £50 confined to Cambridge graduates in Arts, by Miss Shuter in memory of her brother, formerly assistant surgeon to St. Bartholomew's Hospital; and a prize of £10 10s. by Sir F. A. Burrows, Bart., in memory of his father, Sir George Burrows.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, £94 10s. if paid in a single sum on entry, or £105 if paid in five instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery, to the new classes of systematic practical instruction in Medicine and Surgery, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, and Pereira Prize.

Preliminary Science Instruction.—Arrangements have been made for students desirous of undergoing a course of instruction in science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend at the Normal School of Science, South Kensington.

Two Entrance Scholarships, of the value of 100 guineas and 50 guineas respectively, are awarded annually at the commencement of each winter session after a com-

Digitized by Google

petitive examination in the following groups of subjects:—(1) English, including Language, Literature, History, and Geography; (2) Latin and Greek; (3) French and German; (4) Mathematics, including Arithmetic, Algebra, and Geometry; and Mechanics, including Statics and Dynamics; (5) Chemistry (Inorganic) and Physics, including Acoustics, Heat, and Electricity; and (6) Animal and Vegetable Biology. The value attached to each group of subjects is 1000 marks. No candidate may offer himself for examination in more than three of the above groups of subjects, the selection of the groups being left entirely to the candidate. The Scholarships will be awarded by the School Committee to the two candidates who, on the report of the examiners, have shown the highest degree of excellence; but no Scholarship will be awarded unless, in the opinion of the examiners, a satisfactory standard has been attained. In the first four groups the subjects (as regards extent and the authors selected) will be the same as those chosen for the Matriculation Examination of the University of London in the June immediately preceding; in the fifth and sixth, the same as those for the Preliminary Scientific Examination of the same University. Candidates must give notice to the Librarian of their intention to compete, and of the groups in which they offer themselves for examination, on or before Saturday, Sept. 21st, 1889. The examination will commence at the School on Monday, Sept. 23rd, at 10 A.M. The successful candidates will be required to enter for their complete medical education at Charing-cross Hospital, either immediately or at the commencement of the next following summer session.

A Scholarship of the value of 50 guineas is open to students from the University of Oxford who have passed the First M.B. Examination, and to students of the University of Cambridge who have passed the Second M.B. Examination, and who have not entered at any London medical school. Subjects: Anatomy and Physiology, including Histology. The examination for this Scholarship, which will be largely practical, will be held on Sept. 23rd and 24th. Notice to compete must be sent in on or before Saturday, Sept. 21st, 1889. The successful candidate will be required to complete his curriculum at Charing-cross Hospital.—The Llewellyn Scholarship of £25, for students who have just completed their attendance on lectures; and the Golding Scholarship of £15, for students who have just completed their first year. The Pereira prize of £5 is open to all general students, and is awarded annually for the best clinical reports. The Governor's Gold Medal is given for excellence in clinical work. Silver or Bronze Medals, or an equivalent in Books, are awarded to the most distinguished students in all classes; and special prizes in the classes of Dental Surgery, Pathology, and Practical Histology. The Medical School is being considerably enlarged, and, in addition to other improvements, new Physiological and Pathological Laboratories will be erected, and an additional reading and writing room provided for the use of the students.

ST. GEORGE'S HOSPITAL.—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointments of house physician and house surgeon, assistant house physician and assistant house surgeon, ophthalmic assistant, registrar's assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods, free of any charge. Gentlemen are admitted to the hospital practice and lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £20 for each subsequent year of attendance. On payment of the third instalment the pupil may become perpetual, provided that the Dean can certify that his conduct has been satisfactory. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of house physician and house surgeon. Perpetual pupils are eligible for the offices of curator of the museum, medical and surgical registrar, demonstrator of anatomy, and obstetric assistant. These are all salaried offices. The obstetric assistant is resident, with a salary of £100.

Entrance Scholarships.—£125, open to sons of medical men; two of £50 each, open to all students commencing their medical studies; £90, open to students who have passed the Cambridge First M.B.; £65, open to students who have been signed up for or passed the Oxford First M.B. or Cambridge Second M.B.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England within two years previously to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery.—The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession and for moral conduct, open to perpetual pupils in their fourth year of study.—Sir Charles Clarke's Prize (interest of £200 consols) for good conduct; the Brackenbury Prize in Medicine, value £32; the Brackenbury Prize in Surgery, value £32; the Treasurer's Prize, £10 10*s.*; the Thompson Medal; the Brodie Prize for Clinical Surgery; the Acland Prize for Clinical Medicine; the Pollock Prize in Physiology; the Henry Charles Johnson Prize in Anatomy; and General Proficiency Prizes, value £10 10*s.* each, for students of each year.

GUY'S HOSPITAL. — *Appointments:* House physicians, house surgeons, assistant house physicians and assistant house surgeons, obstetric residents, clinical assistants, surgeons' and assistant surgeons' dressers, surgical ward clerks, clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments, are appointed from among the students, upon the recommendation of the medical staff, according to merit, and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physician attends in the Out-patient Department three afternoons in the week, and sees all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the Medical Wards, and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each, and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons. The surgeons' dressers are selected from those students who have completed their third winter session, and have been most diligent in the junior appointments. They usually hold office for six months each. Six are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, two in number, are provided with board and lodging in the hospital free of expense.

Scholarships, Prizes, &c.—Entrance Scholarships in Arts (£131 5*s.* and £52 10*s.*). Subjects: Latin, Greek, French, German, and Mathematics. — Entrance Scholarships in Science (£131 5*s.* and £52 10*s.*). Subjects: Inorganic Chemistry, Zoology, Botany, and Physics. The examination begins on Wednesday, Sept. 25th.—For first-year students: First prize £50, second prize £25, for Anatomy, Physiology, Materia Medica, and Chemistry.—For second-year students: First prize £25, second prize £10, for Anatomy and Physiology. The Sands Cox Scholarship of £15 (tenable for three years) for Physiology. The Michael Harris prize of £10 for Anatomy.—For third-year students: First prize £25, second prize £10, for Medical and Surgical Anatomy, Midwifery, and Therapeutics.—For fourth-year students: First prize £25, second prize £10, for Medicine, Surgery, Midwifery, and Medical Jurisprudence. The Golding Bird prize of £33 for Methods of Diagnosis in Disease.—For senior students: The Treasurer's Gold Medal for Clinical Medicine; the Treasurer's Gold Medal for Clinical Surgery; the Gurney Hoare prize of £25 for Clinical Reports and Commentaries; and the Beaney prize of 30 guineas for Pathology. The Physical Society awards two prizes, each of £5, to the authors of the best Essays on selected subjects, prizes of £10 and £5 for the best papers read before the Society, and a prize of £5 to the member who has most distinguished himself in the debates of the session.

Fees.—1. A perpetual ticket, including admission to lectures, demonstrations, and hospital practice, competition for prizes, and eligibility for hospital appointments, may be

Digitized by Google

obtained—(*a*) by the payment of 125 guineas on entrance; (*b*) by two payments of £66, one on entrance, the other at the commencement of the ensuing session; (*c*) by the payment of three annual instalments, at the commencement of each academical year: first year, £50; second year, £50; third year, £37 10*s*. 2. A reduction is made in the fees for a perpetual ticket in the case of students who have spent one or more years at another medical school. Students entering as second-year students are charged for their first year at Guy's Hospital, £50; second year, £40; third year, £20; or 95 guineas in one sum on entrance. Students entering as third-year students are charged for their first year at Guy's Hospital, £50; second year, £20; or 65 guineas in one sum on entrance. Students entering as fourth-year students are charged for their first year at Guy's Hospital, £50; second year, £5; or 50 guineas in one sum on entrance.

The College.—The College stands upon a site fronting the east gate of the hospital, and is connected with it by a subway. The building has been planned to serve as a Residential College for Students, and at the same time to provide accommodation for the Students' Club. The residential portion consists of rooms for the house physicians, house surgeons, and obstetric residents, together with the following accommodation for other students:—1. Thirty-four sets, each consisting of a sitting-room and bedroom; the rent of each set is 16*s*. a week, if taken for a period of not less than three months, or £39 for the whole year. 2. Two sets, each consisting of a large sitting-room and two bedrooms; the rent of each set is 27*s*. a week, if taken for a period of not less than three months, or £66 for the whole year. 3. Eight single sitting-rooms, with an alcove for the bed; the rent of each room is 12*s*. a week, if taken for a period of not less than three months, or £30 for the year. 4. Four bedrooms and a common sitting-room for the externs, at a charge to each of 10*s*. a week. The rooms are comfortably furnished, and the above charges include attendance, but are exclusive of fire, lighting, and washing. Rents are payable in advance. In the allotment of rooms regard will be had to the length of time for which the student proposes to occupy them, and preference will usually be given to those applying for the longer periods. Every student on coming into residence in the College will be required to become a member of the Students' Club, and to make a deposit of 5 guineas with the Warden, which will be returned to him in full on his leaving the College, unless wilful or careless damage has been done to his rooms or furniture, in which case the whole or a part of the deposit will be retained to make good the damage done. The rooms for the use of members of the Students' Club, in common with the residents in the College, comprise a dining-hall, two large reading-rooms, and ample lavatory accommodation. The Club, which is managed by a committee consisting of members of the medical staff and representatives of the students, is open to all students of the hospital upon payment of an annual subscription of 12*s*. 6*d*., or of a composition fee for life membership of 50*s*. The dining-hall is open from 8 A.M. to 8 30 P.M., and breakfasts, luncheons, and dinners are provided at moderate charges. Residents in the College may either take their meals at the ordinary tariff, or by arrangement with the steward at a charge of 1 guinea a week, payable in advance. In this charge wine and beer are not included. No meals will be served in the students' private rooms. The reading-rooms, which are open from 8 A.M. to 10 P.M., are provided with daily papers, and scientific and other journals. The students residing in the College are under the supervision of a resident Warden, and are required to conform to the rules and regulations made by the College Committee. All inquiries with respect to residence in the College should be addressed to the Warden, The College, Guy's Hospital, S.E.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the ophthalmic clinical assistant, the clinical clerks, and the house surgeons and dressers, are selected by examination from among those matriculated students of the College who are pupils of the hospital. Rooms are provided within the walls of the College for the residence of matriculated students. Rooms and commons are provided at the hospital for the resident officers free of charge.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years for Literature. Three additional Scholarships of £25 per annum each for two years will be awarded this year. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science. Rabbeth Scholarship of £20 per year for Science. College Scholarships: One of £40 per annum for two years; one of £30 for one year; three of £20 for one year. The Daniell Scholarship for Chemistry, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4*s*. The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July. Class Prizes, value £3 3*s*. each, are awarded annually in every subject. A Warneford Scholarship of £25 per annum for two years for third-year subjects is awarded annually to resident students only.

LONDON HOSPITAL AND COLLEGE.—The Medical School of the London Hospital has lately been entirely remodelled and rebuilt. The present buildings were opened by their Royal Highnesses the Prince and Princess of Wales on May 21st, 1887, the accommodation now afforded being more than double that which was provided in the old buildings. The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 8873, out-patients 101,548, and the number of accidents 9769.

The following Scholarships and Prizes will be offered for competition during the ensuing winter and summer sessions:—Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition on September 25th, 26th, and 27th, 1889. The subjects are Physics, Botany, Zoology, and Inorganic Chemistry. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered, and are not eligible to compete for the Buxton Scholarships.—The two Buxton Scholarships, value £30 and £20, will be offered for competition on October 2nd, 3rd, and 4th, 1889. The subjects are those appointed by the General Council of Medical Education and Registration as the subjects of the Preliminary Examination.—A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, will be competed for at the end of the winter session by first and second-year students.—A Scholarship, value £20, in Anatomy and Physiology, for first-year students. (At the commencement of the summer session.) The Letheby Prize, value £30, for proficiency in Chemistry. (At the end of the summer session.) Open to all full students who have completed their second summer session up to the termination of their fourth year from entrance.—A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Medicine. (At the end of the winter session.)—A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Surgery. (At the end of the winter session.)—A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Obstetrics. (At the end of June.)—The Duckworth Nelson Prize, value £10, will be offered biennially for competition at the end of the winter session, and be open to all students on similar conditions to those of the Hospital Scholarships. The subjects of examination will be Practical Medicine and Surgery.—The Hutchinson Prize, value £35, will be given triennially to the author of the best essay upon a subject in Clinical Surgery. Candidates must be full students of the hospital who have not been registered more than ten years.—Out-patients' Dressers' Prizes. Six prizes, of the aggregate value of £60, will be offered for competition at the end of the winter session. Candidates must pass an examination in Minor Surgery, have dressed diligently for twelve months, and have passed the Primary Examination of the Royal College of Surgeons.—Two Dissection Prizes, value £6 and £4.

Special classes are held throughout the year for the Preliminary Scientific Intermediate M.B. Examinations of the University of London and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Special entries can also be made for Medical and Surgical Practice, the Operative Surgery classes, &c.

In addition to the regular courses of lectures, there will be given during the winter and summer sessions a course of

Digitized by Google

lectures on Clinical Medicine by Sir Andrew Clark, Bart., F.R.S., Emeritus Professor of Clinical Medicine, and a course of lectures on Clinical Surgery by Mr. Jonathan Hutchinson, F.R.S., Emeritus Professor of Clinical Surgery.

During the summer session a course of lectures will be delivered on Pathological Chemistry by Dr. C. H. Ralfe, Physician to the Hospital, on Mondays, at 4 P.M.

ST. MARY'S HOSPITAL.—There are three House Physicians and three House Surgeons, each appointed for six months, and two Obstetric Officers, each appointed for six months. They board free of expense in the hospital, except that the obstetric officer resides outside the hospital at his own expense for the first three months. These appointments are awarded after competition, without additional fee. Two Demonstrators of Anatomy are appointed annually, with a salary of £70 and £50 respectively; and a Demonstrator of Physiology, at £120 a year. All these officers are eligible for re-election. There is also a Demonstratorship in Pathological Anatomy, of the value of £15, and tenable for six months; the holder of this scholarship will assist the pathologist in the discharge of duties in the museum and deadhouse. Two Prosectors of Anatomy and two Assistant Demonstrators of Physiology are appointed annually, and receive a certificate and £5 each for satisfactory service in their respective departments. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. In addition to the instruction given in the wards daily, special Clinical Lectures are given on Fridays throughout the academical year, at 4 P.M. The hospital contains 281 beds. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases. There is an out-patient department for diseases of children.

Scholarships, Prizes, and Appointments: Scholarships offered for open competition previously to entering at the Medical School.—Entrance Scholarships: The following will be offered for competition on Sept. 26th and 27th, at 10 A.M.—One Scholarship in Natural Science, of the value of 100 guineas, open to any gentleman who has not completed a winter session of study at a medical school. Three Scholarships in Natural Science, each of the value of 50 guineas, under the same conditions. One Scholarship of the value of 100 guineas, open to students from Epsom College, being sons of medical men, and who have not completed a winter session of study at a medical school. This Scholarship is not given by competition. Two Scholarships, each of 50 guineas, open to students from the Universities of Oxford, Cambridge, or other University, who have not entered at any London medical school. The examination for the Scholarships will be conducted according to the syllabus of the Preliminary Scientific Examination of London University. A Scholarship in Mathematics and one in Classics, each of the value of £50, will be open to competition on April 30th, 1889, to students who enter in May, 1889.

In addition to the Open Entrance Scholarships, Class Prizes, and usual Appointments, Scholarships will be offered for competition at the end of each year, open to all pupils. These Scholarships are of the value of £20, £25, and £30, for the first, second, and third years respectively.

A residence for students, 33 and 35, Westbourne-terrace, W., in connexion with the hospital, is under the charge of a warden, Dr. Luff, who is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: 90 guineas for the academical year, to *include special instruction by the Demonstrators on three evenings a week.*

MIDDLESEX HOSPITAL.—There is a special Cancer Department, affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in Medicine, Midwifery, in the microscopical examination of Healthy and Diseased Tissues, and also in the application of Bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the School. The museum has recently been rearranged, and a complete catalogue prepared of the various specimens. Two Entrance Scholarships, of the annual value of £50 and £30, and tenable for two years, are offered for competition at the commencement of the winter session. An Exhibition in Elementary Anatomy, Osteology, and Physiology, value £10 10*s.*, is awarded to students at the end of their first year. The Lyell Medal is awarded annually for proficiency in Surgical Anatomy and Practical Surgery. The Hetley Prize is awarded annually for Clinical proficiency. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, are awarded to those students who pass the best examination at the bedside and in the post-mortem room. The Murray Medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital; it will be next awarded in May, 1892. The Governors' Prize of 20 guineas is also awarded annually to the student after his third winter session who shall pass the best clinical examination in the out-patient departments. Valuable class prizes are also given, and sixteen resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education and complied with the regulations of the School.

Arrangements have been made for students desirous of undergoing a course of instruction in Science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend such a course at the Normal School of Science, South Kensington. Fee for the whole course, £35. Students who enter for this course will be allowed a deduction of £20 on the fees for the medical curriculum.

The *Residential College*, which can accommodate about thirty students, adjoins the Medical School. The resident warden assists the students in their studies.

The following are the regulations of the College relating to the residence and board of the students: Students are received for residence at a charge of 10 guineas per term, exclusive of fire, lights, and washing. Students are required to dine in the Hall, and the charge for dinner (not including beer) is 10*s.* 6*d.* per week. Breakfast and luncheon can be obtained in the College Hall at the daily tariff, which will be found on the breakfast and luncheon lists. N.B.—There are a few rooms on the fourth floor, for which the charge is 8 guineas per term.

During the past year the School has lost two of its oldest and warmest friends in the deaths of Dr. Headlam Greenhow, consulting physician, and Major A. H. Ross, chairman of the Weekly Board of the Hospital. Dr. Greenhow retired from the acting staff about nine years ago, but he continued to take a keen interest in the institution which he had served for many years. Major Ross had been chairman for nearly twenty years, and had carried out many improvements in the management of the hospital. To him is owing the foundation of a Trained Nurses' Institute in connexion with the Middlesex Hospital, whilst the construction of the Residential College was largely owing to his personal influence and support. The vacancy created by Major Ross's death has been filled by the election of Lord Sandhurst to be chairman of the Board. A new feature is the formation of classes in Advanced Physiology (Mr. Lowne) and Morphology (Mr. Bland Sutton) for those students who are engaged in preparing for the Higher Examinations.

ST. THOMAS'S HOSPITAL.—*Prizes and Appointments for the year 1889-90.*—For First-year students: Two Entrance Scholarships in Natural Science of the value of 125 guineas and £60 respectively, open to all first-year students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology, at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 consols, is awarded each year; also prizes of £20 and £10; summer, £15 and £10. For Second-year students: The Peacock Scholarship of £38 10*s.*, and the Musgrove Scholarship of £38 10*s.*, are awarded biennially to the students who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations: making the winter prizes £38 10*s.*, £20, and £10; summer, £15 and £10; with the dresserships and the clinical clerkships. For Third-year students (winter): Second tenure of Scholarship, £38 10*s.*, and

Digitized by Google

prizes of £20, £15, and £10; summer, £15 and £10. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £15 annually is awarded to students, who must be from three to six years' standing, for the best Anatomical or Physiological Essay, to be illustrated by preparations and dissections. The Cheselden Medal for Surgery and Surgical Anatomy, and the Mead Medal for Practical Medicine, are awarded annually to fourth-year students. The Solly Medal, with a prize of from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of surgical cases. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year student.

Classes in Practical and Operative Surgery are held four times a week for six weeks prior to the final examinations of the Examining Board in January, April, and July. In connexion with these classes, Clinical Instruction is given in the wards by the resident assistant surgeon, and a course of Demonstrations on Museum Specimens is given by the curator, Mr. Shattock.

UNIVERSITY COLLEGE, LONDON.—*Composition Fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 120 guineas, if paid in one sum at the commencement of the course; 125 guineas, if paid by instalments, as follows—first year, 55 guineas; second year, 50 guineas; third year, 20 guineas. 2. For those students who do not require to attend Chemistry, Pharmacy, and Materia Medica at a medical school (under the regulations of the Examining Board in England) the fee will be—100 guineas, if paid in one sum; 105 guineas, if paid by instalments, as follows—first year, 50 guineas; second year, 35 guineas; third year, 20 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 50 guineas. 4. For the course of instruction for the Final M.B. Examination of the University of London, 70 guineas, if paid in one sum; 72 guineas, if paid by instalments, as follows—first year, 40 guineas; second year, 32 guineas. 5. Composition fee for Dental Students, 60 guineas. 6. Composition fee for the whole course of instruction for the Preliminary Scientific (M.B.) Examination of the University of London, 35 guineas.

Exhibitions, Prizes, &c.—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics, Botany, and Zoology. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £105 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. The Cluff Memorial Prize, value about £15, every second year to the most proficient in Anatomy, Physiology, and Chemistry. The Erichsen Prize: a surgeon's operating case of the value of £10 10*s.*, awarded yearly to the student of the class of Practical Surgery who shall most distinguish himself by manipulative skill. The Morris Bursary of £25 a year, tenable for two years. Besides the above, gold and silver medals and other prizes are awarded in each class.

Several professors and other gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons unconnected with the College who receive boarders into their families; among these are several medical gentlemen.

The annual dinner of the old and present students of the Faculty of Medicine will be held in the General Library of the College on Tuesday, Oct. 1st, at 6.30 P.M. William Cadge, Esq., F.R.C.S., will preside.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women, and a special ward for Children. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

A curator of the museum and a pathologist, each with a salary of £50, and a medical and surgical registrar, each with a salary of £40, are appointed annually. Two house physicians, two house surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons. Clinical assistants to the physicians and surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

Scholarships and Prizes.—A Science Scholarship, value £100, is offered annually; the Guthrie and Entrance Scholarships, on alternate years, value £80; and two Entrance Scholarships, value £40. Entrance Scholarship, summer session, value £40. A £20 Entrance Scholarship is offered annually to Dental Students. The Treasurers' Prize, an Exhibition in Anatomy, Physiology, and Chemistry, value £10 10*s.*, tenable for one year for first-year men. The President's Prize, a Scholarship in Anatomy, Histology, and Physiology, value £21, given by his Grace the Duke of Westminster, President of the Hospital, to a student of the second year (to be styled Assistant Demonstrator). At the end of the fourth winter session, prizes of £5 each (books or instruments) in Clinical Medicine and Clinical Surgery, Frederick Bird Medal and Prize, value £15. Subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth. In most of the classes special prizes, value about 2 guineas each, are given by the lecturers.

METROPOLITAN ANCILLARY SCHOOLS OF MEDICINE.

The following institutions offer a partial curriculum in the form of classes dealing with particular subjects, or adapted to special circumstances.

BETHLEM HOSPITAL.—This hospital is open for the admission of two Resident Clinical Assistants who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, and will be provided with such apartments, rations, and attendance as the Committee shall consider reasonable. They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms £3 3*s.* for three months; six months, £5 5*s.*; perpetual £10 10*s.* Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

CENTRAL LONDON THROAT AND EAR HOSPITAL.—The hospital contains accommodation for seventeen in-patients, and has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 6257 out-patients and 230 in-patients were treated. Fee for three months' attendance, 2 guineas; for six months', 3 guineas. A course of lectures on the special diseases treated at this hospital will be delivered during the winter months by members of the staff. The date of these lectures is announced in the medical journals prior to their commencement. They are free to qualified practitioners and advanced students of medicine. Consulting Surgeon: Mr. Sydney Jones. Surgeons: Mr. Lennox Browne, Dr. Arthur Orwin, Dr. J. Dundas Grant, and Mr. Percy Jakins. Assistant Surgeon: Mr. T. W. Carmalt Jones. Dental Surgeon: Mr. George Wallis. Defects of Speech: Mr. William Van Praagh. Secretary: Mr. Richard Kershaw.

HOSPITAL FOR WOMEN, CHELSEA.—Established 1871. The hospital contains sixty-three beds. Qualified medical men are admitted to see the practice of this hospital, and post-graduate course of lectures is delivered.

Digitized by Google

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road. (Instituted 1816.)—Consulting Physicians: Dr. Wilks, Dr. John Williams, Dr. G. V. Poore, and Dr. Geo. Roper. Consulting Surgeon: Arthur Durham. Physicians: Drs. W. A. Duncan, Alex. Haig, Septimus Sunderland, and W. R. Dakin. Surgeon: Mr. H. C. Jacobson. Assistant Surgeon: Mr. E. Overman Day. Surgeon-Dentist: Mr. Alfred Barnard. Resident Medical Officer: Mr. Henry B. Brackenbury. Secretary: Mr. R. G. Kestin. Advanced students in Medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5*s.* must be paid to the physicians and surgeons in ordinary conjointly.

HOSPITAL FOR WOMEN, Soho-square, W. — In connexion with this institution there has been for some years a well-organised Clinical Department, which has lately been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women, gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their third year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large numbers of out-patients afford quite unrivalled opportunities for practical instruction in the use of gynæcological instruments, and for the study of diseases peculiar to women. A course of lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each quarter by a member of the Staff. Clinical lectures are given in the Operating Theatre on alternate Thursdays, throughout the winter and summer sessions. Valuable prizes are given, after examination, annually, open to past and present clinical assistants. Fee for the three months' course, £8 8*s.* Any further information can be obtained by letter, addressed to the Dean at the hospital.

MR. THOMAS COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, SURGERY, &c.—By decision of the Royal Colleges of Physicians and Surgeons, gentlemen rejected at their Anatomical and Physiological Examinations (Primary R.C.S., or Second Conjoint) can get "signed up" from this school for the three or six months' work they are now required to put in before re-examination. This school is intended to meet the requirements of two classes of students: 1. Qualified practitioners and advanced students—i.e., gentlemen wishing either to obtain some of the higher qualifications, or to compete for appointments in Her Majesty's Army, Navy, and Indian Medical Services. 2. Students preparing for the usual Primary and Pass Examinations of any of the licensing bodies. The instruction is given on the dissected and undissected body, with normal and pathological specimens, microscopical preparations, chemical, physiological and surgical apparatus, splints, &c. The school possesses a good collection of physiological apparatus, allowing of the demonstration to the class of the great bulk of the usual practical exercises in Physiology; also chemical apparatus, allowing every student not only to see, but to repeat for himself, the analysis of the principal food-stuffs, and fluids and solids of the body, and also all the usual reactions, tests, &c. Gentlemen preparing for the Higher Examinations receive special instruction in the more difficult subjects, and have the advantage of personally repeating the practical exercises in Physiology above alluded to. The operations of Surgery are performed by the students on the dead body. Private address: 40, Brunswick-square.

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL, Leicester-square. — Lectures are delivered, in winter, on Mechanical Dentistry, by Mr. David Hepburn, on Wednesdays, at 5 P.M.; in summer, by Mr. Storer Bennett, on Dental Surgery and Pathology, on Tuesdays and Fridays, at 8 A.M., and by Mr. Arthur Underwood, on Dental Anatomy and Physiology (Human and Comparative), on Wednesdays and Saturdays, at 8 A.M. *Fees:* General fee for special lectures required by the curriculum, £15 15*s.*; fees for two years' hospital practice required by the curriculum, £15 15*s.*; total fees for lectures and practice, £31 10*s.*; perpetual fees, £36 15*s.* Hospital Surgeons: Messrs. Canton, Gregson, Truman, Storer Bennett, Claude Rogers, and Woodhouse. Assistant Surgeons: Messrs. Hern, Matheson, Parkinson, Read, Rogers, Paterson, and E. Lloyd Williams. Anæsthetists: Messrs. Braine, Bailey, Bird, and Mills. Assistant Anæsthetists: Drs. Buxton and Hewitt. Medical Tutor: Mr. H. Baldwin. All communications to be addressed to Mr. Morton Smale, Dean.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (Established 1814.)—This hospital has recently been enlarged by the addition of a very complete out-patients department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

ROYAL EAR HOSPITAL, Frith-street, Soho-square, W. (Founded 1816, for the special treatment of Diseases of the Ear.)—During 1888, 94 in-patients and 2760 out-patients were treated. The clinique of the hospital is open to medical practitioners and advanced students by previous arrangement with the Secretary. Surgeons: Dr. Urban Pritchard and Mr. Farquhar Matheson. Secretary: Mr. M. C. Puddy.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road. Consulting Physician: Sir Andrew Clark, Bart., M.D. Consulting Surgeons: Frederick le Gros Clark and W. S. Savory. Physicians: Drs. Cholmeley, Burnet, Beale, Beevor, Syers, and Galloway. Obstetric Physicians: Drs. W. S. A. Griffith and Dakin. Surgeons: Messrs. W. Adams, Macready, Lockwood, H. W. Allingham, and C. E. H. Cotes. Ophthalmic Surgeon: Mr. Jonathan Hutchinson, jun. Aural Surgeon: Mr. W. R. H. Stewart. Throat Department: Mr. W. Spencer Watson. Skin Department: Dr. Cook. Dental Surgeon: Mr. E. Keen. The new buildings in the Holloway-road have recently been completed, and the practice of the hospital is open to qualified practitioners and senior students. Clinical assistants are appointed in the wards and out-patient department. Further information can be obtained on application to the Hon. Secretary of the Medical Committee, 57, Welbeck-street, W.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital founded in 1804, and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by 2196 persons. The out-patients are yearly over 25,000; attendances, 126,305 in 1887. Operations are performed daily from 10.30 to 1 o'clock, and three surgeons attend on each day. Students are admitted to the practice. Fee for six months, £3 3*s.*; perpetual, £5 5*s.* Classes, demonstrations, and lectures are periodically given, to which perpetual students are admitted free. Students of the hospital are eligible for the office of house surgeon, or may be appointed clinical assistants. The Secretary, Mr. Robert Newstead, will furnish further information, as may be desired.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873.)—Physicians: Dr. James Edmunds, M.R.C.P., Dr. J. J. Ridge. Surgeon: Dr. W. J. Collins, F.R.C.S. Dental Surgeon: Mr. A. Alexander. The hospital contains 70 beds. The in-patients average 700 and the out-patients 3000 a year. The medical and surgical practice of the hospital is open to students and practitioners. Special departments for Ophthalmology and Gynæcology. Classes will be held during the winter and summer sessions for students preparing for the final examinations at the Colleges and the Universities. Fees for courses in all subjects from £5 5s. a month. Appointments, vacancies for which are advertised in the medical journals: Registrar and Pathologist, senior and junior House Surgeons. For particulars as to hospital practice and classes apply at the hospital to Dr. W. J. Collins.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—The new hospital, with the Finchley branch, contains 170 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2.30 P.M. In- and out-patient practice and electrical-room treatment at that hour. Physicians: Drs. Ramskill, Hughlings Jackson, Buzzard, and Bastian. Physicians for Out-patients: Drs. W. R. Gowers, D. Ferrier, Ormerod, and Beevor. Assistant Physicians: Drs. James Anderson and Tooth. Surgeons: Messrs. W. Adams and Victor Horsley. Ophthalmic Surgeons: Messrs. R. Brudenell Carter and Marcus Gunn. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Dr. Felix Semon. Anæsthetist: Dr. Silk. Pathologist and Registrar: Dr. W. S. Colman. House Physicians: Drs. I. Risien Russell and James Taylor. Medical practitioners and senior students may attend the practice after signing their names in the clerk's office.

NORMAL SCHOOL OF SCIENCE AND ROYAL SCHOOL OF MINES, Jermyn-street.—Biology: Professor Huxley, Mr. Howes, and Dr. Scott. Chemistry: Dr. Thorp and Dr. Jupp. Physics: Professor Rücker. The course of this

Digitized by Google

school is especially adapted to assist students preparing for the Preliminary Scientific (M.B.) Examination of the University of London.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street.—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Balkwill. Assistant-Surgeon: Mr. H. F. Baker. House-Surgeon: Mr. A. Lyndon. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: six months, £3 3*s.*; twelve months, £5 5*s.*; perpetual, £10 10*s.*

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physician: Dr. Brodie. Consulting Surgeons: Mr. H. Lee and Sir William MacCormac. Physicians to In-patients: Dr. W. Hope and Dr. W. C. Grigg. Physician to Out-patients: Dr. W. S. A. Griffith. This hospital, which has been recently enlarged, receives nearly 1000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—upwards of three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all universities, colleges, and licensing bodies. Midwives and Monthly Nurses are trained. The Midwives are specially prepared for the examination of the Obstetrical Society, and the fees are paid by the hospital for those who obtain the Society's diploma and have previously passed an examination by the physicians of the Hospital. Fees: Medical Students, £3 3*s.* for one week; £5 5*s.* for two weeks; £6 16*s.* 6*d.* for four weeks, exclusive of board and lodging. Pupil Midwives, £26 5*s.* for three months; Pupil Nurses, £15 15*s.* for twelve weeks, and £11 0*s.* 6*d.* for eight weeks; these include board and lodging. For further particulars, application should be made to Mr. G. Owen Ryan, Secretary, at the hospital.

ST. PETER'S HOSPITAL FOR STONE (established 1860).—This hospital contains 24 beds and 3 private wards. Medical men and advanced students are admitted free of charge to see the practice.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: Professor Dunstan, M.A., F.I.C., F.C.S. Practical Chemistry: Professor Attfield, Ph.D., F.R.S., F.I.C., F.C.S.; F. W. Short, Demonstrator; H. D. Fuge, Assistant Demonstrator. Botany: Professor Green, M.A., B.Sc., F.L.S. Materia Medica: Mr. Holmes, F.L.S. Practical Pharmacy: Joseph Ince, F.L.S., F.C.S. The session commences on Wednesday, Oct. 2nd, at 10 A.M. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures &c., and to a course of practical chemistry of any length in the laboratories. Application for admission to the school, or for further information, may be made to the professors or their assistants, 17, Bloomsbury-square, London, W.C. Professor Marshall, F.R.S., F.R.C.S., will deliver an introductory address on Wednesday, Oct. 2nd, at 8 P.M.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich, S.E.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students. Honorary Consulting Physicians: Dr. Robert Barnes, F.R.C.P., and Dr. Richard Quain, F.R.C.P. Visiting Physicians: Dr. John Curnow, F.R.C.P., and Dr. John Anderson, C.I.E., M.R.C.P. Honorary Consulting Surgeon: Mr. J. N. Davies-Colley, F.R.C.S. Visiting Surgeon: Mr. G. Robertson Turner, F.R.C.S. Principal Medical Officer: Mr. W. Johnson Smith, F.R.C.S. House Physician: Dr. Otto J. Kauffmann, M.R.C.P. House Surgeon: Mr. R. Ritson, M.R.C.S. Secretary: Mr. P. Michelli.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, W.C., and Cromwell House, Highgate.—There are now 121 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total, 173. In-patients last year, 1100; out-patients, 17,156. Particulars as to the times of Medical and Surgical Visits and the Practice of the Hospital can be had on application to the Secretary.

SOUTH LONDON SCHOOL OF PHARMACY, LIMITED.—This School was established in 1868, and incorporated in 1888 as a public company. The whole institution is now under the control of the managing director, Dr. John Muter, M.A., F.R.S.E., F.C.S., F.I.C., who lectures on Chemistry, Physics, and Botany. The other lecturers are: Mr. W. H. Dodd, F.C.S. (Materia Medica and Pharmacy); Mr. L. De Konnigh, F.I.C., F.C.S. (Analytical Chemistry); and Mr. T. Townsend, A.P.S., and Lond. Matric. (Classics, Mathematics, and Mechanics); assisted by a staff of competent demonstrators. The department most valuable to medical students is the Medical and General Science Tutorial Department. The subjects taught are:—For Matriculation and Medical Preliminaries: all subjects. For First B.Sc. and Preliminary Scientific: Inorganic and Practical Chemistry. For First M.B.: Organic Chemistry, Analysis, and Pharmaceutical Chemistry and Materia Medica. For Apothecaries' Hall and Royal Colleges of London and Edinburgh: Chemistry, Botany, and Materia Medica. For Pass M.B. Lond.: Practical Toxicology and Forensic Medicine. For Sanitary Science qualifications: Practical Chemistry, Physics, and Microscopy. Particulars as to fees may be had from the Secretary, 325, Kennington-road, London, S.E.

THE COLLEGE OF STATE MEDICINE, London.—The objects of the College, which was founded in 1886 and incorporated in 1887, are—(*a*) to found, establish, and maintain in or near London an institution to aid the theoretical and practical investigation and study of sanitary science, and of all matters relating thereto; (*b*) to aid the theoretical and practical investigation and study of other branches of State Medicine; (*c*) with a view to effecting these objects, to appoint professors, to institute lectures and demonstrations, to issue publications of the Transactions of the Association, and to found chemical and pathological laboratories and a library; (*d*) to do all such other things as may from time to time be incidental or conducive to the attainment of the objects above set forth or any of them. The importance and necessity of such an institution have been forcibly impressed upon the notice of the Council—(1) by the increasing demand for Public Health qualifications; (2) by the fact that possession of such a diploma is of great value to army medical officers, as it gives exemption to this subject in the qualifying examinations for promotion; (3) that the possession of such a diploma is, in accordance with the provisions of the County Government Act, compulsory in the future upon those seeking appointments as medical officers of health. Further particulars as to the courses of lectures &c. may be obtained from the Hon. Secretary, at the College, Great Russell-street, Bedford-square.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen at 1 o'clock, and operations performed daily at 2 o'clock. The following are the days of attendance of the surgeons: Mr. Power (Consulting Surgeon); Mr. Rouse, Tuesday and Saturday; Mr. Macnamara and Mr. Frost, Monday and Thursday; Mr. Cowell, Mr. Juler, and Mr. Wainewright, Wednesday and Saturday; Mr. Hartridge, Tuesday and Friday. The practice of the hospital is open to students. Fees for six months, £3 3*s.*; perpetual, £5 5*s.* Students of the hospital are eligible for the post of house surgeon. Special demonstrations and lectures will be given during the session. Secretary: Mr. T. Beattie-Campbell.

The following hospitals afford facilities for Clinical observation:—

ALL SAINTS CHILDREN'S HOSPITAL, 4, Margaret-street, and 59, Mortimer-street, W.—Founded by the All Saints Sisterhood in 1882 for Chronic Joint Diseases. Twelve beds for boys and eight for girls under the age of ten years.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, and Dr. H. Radcliffe Crocker. Surgeons: Mr. R. W. Parker and Mr. L. A. Dunn. Assistant Physicians: Dr. J. A. Coutts and Dr. Dawson Williams. Assistant Surgeon: Mr. W. H. Battle. Administrator of Anæsthetics: Mr. Thomas Bird. Resident Medical Officer: Mr. E. B. Hastings. Secretary: Ashton Warner. Lady Superintendent: Miss F. A. Davies. Matron: Mrs. Fisher. The hospital maintains 102 cots, and on an average 100 out-patients are seen daily.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physicians: Dr. W. S. Playfair and Dr. James F. Goodhart. Consulting Surgeons: Mr. W. Morrant Baker and Mr. H. G. Howse. Physicians:

Digitized by Google

Drs. Fred. Taylor, Nestor Tirard, Fred. Willcocks, and G. A. Carpenter. Surgeons: Messrs. R. Clement Lucas, G. H. Makins, F. S. Eve, and J. H. Targett. Ophthalmic Surgeon: Dr. W. A. Brailey. Dental Surgeon: Mr. R. Denison Pedley. House Surgeon: Mr. G. H. Pennell. Registrar and Chloroformist: Mr. L. A. Bidwell. Hon. Secretary: Dr. I. Dobree Chepmell.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate.—The hospital contains 70 beds and 12 at the home at Margate, and has a large out-patient department (over 500 weekly). Consulting Physician: Dr. W. H. Walshe. Consulting Surgeons: Mr. Erichsen and Mr. Cowell. Physicians: Dr. Ridge Jones and Mr. T. Colcott Fox. Physicians to the out-patients: Drs. F. D. Drewitt, Henry Philpot, M. Murray, and Walter Carr. Surgeons: Messrs. Pick and Clutton. Surgeons to the out-patients: Messrs. Walter Pye and D'Arcy Power. Ophthalmic Surgeon: Mr. W. A. Frost. Dental Surgeon: Mr. Francis Fox. House Surgeon: Mr. W. H. C. Staveley. House-Physician: Mr. W. W. Ord. Secretary: Captain W. C. Blount, R.N. Out-patients are seen daily as under:—Medical cases: Monday only at 9 A.M.; and every afternoon at 1.30. Surgical cases: Daily, except Wednesday and Saturday, at 9.30 A.M. Dental cases: Saturdays, at 9 A.M.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 101 beds. About 1300 in-patients and 16,000 out-patients, whose attendances number nearly 50,000, are treated annually. There are appointments for a House Physician and two House Surgeons, with board and residence tenable for six months. Also appointments for a limited number of Clinical Assistants. Physicians: Drs. D. W. C. Hood, F. G. D. Drewitt, and W. P. Herringham. Physician for Diseases of Women: Dr. Albert Venn. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and W. Bruce Clarke. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant Physicians: Drs. J. B. Ball, Seymour Taylor, and A. E. Garrod. Assistant Physician for Diseases of Women: Dr. J. A. Mansell Moullin. Assistant Surgeons: Messrs. C. A. Ballance, H. F. Weiss, and S. Paget. Assistant Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Surgeon-Dentist: Mr. H. L. Albert. Pathologist: Mr. H. P. Dunn. Physician in charge of Throat and Nose Department: Dr. J. B. Ball. Aural Surgeon: Mr. S. Paget. Physician to Skin Department: Dr. F. G. D. Drewitt. Surgeon to Skin Department: Mr. H. F. Weiss. Surgeon in charge of Orthopædic Department: Mr. C. B. Keetley. Physician in charge of Electrical Department: Dr. W. P. Herringham. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Secretary: Mr. R. J. Gilbert.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE, BIRMINGHAM.—The Sands Cox Prize, of the value of £20, is offered annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. Two Ingleby Scholarships are offered annually after examination in Obstetric Medicine and Surgery and Diseases of Women and Children. The Scholarships are open to students who have completed two years of their curriculum in this College. One or more Sydenham Scholarships will be offered annually, of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. The Scholarships are held for three years, subject to good behaviour. One or more Queen's Scholarships will be offered annually, of the value of 30 guineas. They are held for three years, one-third being paid each year, subject to good behaviour. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. Students of Queen's College are qualified to compete for all scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM.—*General Hospital:* Consulting Physician: Dr. Fletcher. Consulting Surgeons: Mr. Crompton and Mr. Baker. Physicians: Drs. Wade, Foster, Rickards, and Saundby. Surgeons: Messrs. Pemberton, Bartleet, Jolly, and Chavasse. Obstetric Officer: Dr. Malins. Assistant Physicians: Drs. Simon and Foxwell. Assistant Surgeons: Messrs. Haslam and Barling.—*Queen's Hospital:* Consulting Physician: Sir Jas. Sawyer. Consulting Obstetric Surgeon: Mr. John Clay. Consulting Surgeon: Mr. Furneaux Jordan. Physicians: Drs. Carter and Suckling. Surgeons: Messrs. Wilders, Bennett May, Jordan-Lloyd, and Marsh. Obstetric Surgeon: Vacant. Ophthalmic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims. Casualty Surgeons: Messrs. Clay and Morrison.

MASON COLLEGE, BIRMINGHAM. (Founded 1875. Opened 1880.)—The session will commence on October 1st. Instruction is given in Arts and Science, and students are prepared for the various examinations of the University of London. Entrance and other Scholarships and Prizes are offered for competition. This College is associated with Queen's College, Birmingham, for the purposes of medical education, all students of the latter College attending in the Physical, Chemical, Zoological, Botanical, and Physiological Departments of Mason College. The Library contains upwards of 19,000 volumes. A syllabus containing full information as to the various courses of instruction, fees, &c., will be forwarded on application to the Secretary.

BRISTOL SCHOOL OF MEDICINE (affiliated to University College, Bristol).—Students can complete in Bristol the entire course of study required for the Medical and Surgical Degrees of the University of London, and for the Diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given at University College, Bristol, are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; while the Medical School, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the above examining boards. All necessary information may be obtained from the Dean of the Bristol Medical School, Dr. Markham Skerritt.

BRISTOL ROYAL INFIRMARY (founded 1735).—264 beds. Physicians: Drs. Shingleton Smith, Waldo, Shaw, and Prowse. Surgeons: Messrs. Board, Prichard, Greig Smith, Harsant, and Bush. Ophthalmic Surgeon: Mr. Cross. Obstetric Physician: Dr. Wedmore. Dental Surgeon: Mr. Ackland. Assistant Physician: Dr. Williams. Assistant Surgeon: Mr. Munro Smith. House Surgeon: Dr. Swain. House Physician: Mr. Hill. Secretary: Dr. Shekelton.

Scholarships and Prizes.—Two Entrance Scholarships, 35 guineas and 10 guineas, awarded annually in October, after examination in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clark Prize, 15 guineas; Crosby Leonard Prize, 7 guineas; Tibbitts Prize, 9 guineas; Midwifery Prize, 3 guineas in books; Six Pathological Prizes, 3 guineas each.

Dressers reside in the house in weekly rotation, and have charge of all casualties under the supervision of the house surgeon. Special instruction (including dresserships) for first-year students in the out-patient department. Class instruction in the wards by the physicians and surgeons on five days a week, in addition to the regular clinical lectures. Clinical Clerkships and Dresserships, 5 guineas for each six months. Perpetual Medical and Surgical Practice, 35 guineas in one sum. Special departments for Diseases of Women, the Eye, Ear, &c., with Clerkships and Dresserships attached. One or two Pathological Clerks are appointed every four months, who perform all post-mortem examinations. There is a large museum and well-stocked library.

Further information can be obtained from Dr. Arthur B. Prowse, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—200 beds. Physicians: Drs. Markham Skerritt, Harrison, and Baron. Physician-Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Dobson, and Pickering. Dental Surgeon: Mr. Parson. Assistant Physician: Dr. Clarke. Assistant Surgeon: Mr. Barclay. House Surgeon: Dr. Newnham. Physicians' Assistant: Mr. Hill. Assistant House Surgeon: Mr. Griffiths. Clinical Clerkship, six months, £5 5s. Dresserships, six months, £5 5s. Obstetric Clerkship, three

Digitized by Google

months, £3 3s. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women and in Dental Surgery. Further information may be obtained of the Secretary, at the hospital, or from Dr. Markham Skerritt, Dean of the Hospital Faculty.

Scholarships and Medals. — Lady Haberfield Entrance Scholarship: This scholarship, founded in 1875, of the value of 30 guineas, the interest of £1000, bequeathed for the purpose by the late Lady Haberfield, is awarded annually at the commencement of the winter session, after a competitive examination in subjects of general education. Second Entrance Scholarship: An additional Entrance Scholarship of the value of £20 is awarded when more than six candidates present themselves. Clarke Scholarship: A Surgical Scholarship, of the value of £15, founded by H. M. Clarke, Esq., of London, is awarded annually at the end of the winter session, after an examination in Surgery. Sanders Scholarship: A Scholarship founded by the late John Nash Sanders, Esq., of the value of £22 10s., is awarded annually at the end of the winter session, after examination in Medicine, Surgery, and Diseases of Women. Martyn Memorial Pathological Scholarships, founded in 1878, by public subscription, in memory of the late Dr. Samuel Martyn, Physician to the Hospital. Two Scholarships, each of the value of £10, are awarded annually; one at the end of the summer session, and one at the end of the winter session. A student may, at the option of the Faculty, hold both these Scholarships. After a competitive examination in Pathology and Morbid Anatomy, the successful candidate is appointed Pathological Clerk to the hospital for the term of six months. Committee Gold Medal: This medal, presented by the committee of the hospital, is awarded annually at the end of the winter session to the student of the fourth year who has most distinguished himself during his career at the hospital and medical school. Committee Silver Medal: This medal, presented by the committee of the hospital, is awarded annually at the end of the winter session to the next most distinguished student of the fourth year. The rules relating to the several Scholarships may be had on application.

ADDENBROOKE'S HOSPITAL, Cambridge.—Clinical Lectures in Medicine and Surgery, in connexion with the Cambridge Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:—A University of Durham Scholarship, value £100, for proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value £15, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest of £500, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680. At the end of each session a Prize of Books and Honours Certificates are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, an Assistant Curator of the Museum, Prosectors, and Assistant Physiologists are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Clinical Clerks, and Dressers are appointed every three months

ROYAL INFIRMARY, Newcastle-upon-Tyne.—Physicians: Drs. Philipson, Drummond, Oliver, and Limont. Surgeons: Drs. Arnison and Hume, Mr. Page and Mr. Williamson. Assistant Surgeons: Mr. T. A. Dodd and Mr. James Rutherford Morison. Pathologist: Dr. Drummond. Dental Surgeon: Mr. R. L Markham. House Physician: Dr. W. Baigent. The infirmary contains 280 beds. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given as opportunity offers by the Pathologist. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Coxlodge Lunatic Asylum. A Special Course of Instruction is given in the City Hospital for Infectious Diseases by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong. Secretary, Mr. J. Henry Rutherford.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 320 in-patients, surgical and medical, and during the last year 4428 in-patients and 30,985 out-patients were treated; these numbers show a remarkable increase if compared with statistics of ten years ago, when only 11,500 out-patients were seen. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in the operating-room. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students.

The Leeds Medical School, now the Medical Department of the Yorkshire College, occupies a central position in the town, close to the General Infirmary, and a few minutes' walk from the buildings of the Science and Art Departments situated in College-road. The teaching in Chemistry and Physics, Practical Chemistry, Practical Toxicology, Biology, Practical Pharmacy, and Botany is given in the College-road buildings, the lecture-rooms and laboratories of which are amongst the most commodious in the kingdom. The accommodation for teaching comprises all the conveniences necessary for the various branches of study. All the other courses required by the examining boards are given by Professors and Lecturers. The Museums and Library offer special advantages. Two Entrance Scholarships are offered: one, of the value of 60 guineas, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students: Resident medical officer, resident surgical officer, resident obstetric officer, appointed for twelve months and eligible for re-election; two house physicians, holding office for twelve months; four house surgeons, for twelve months; twenty-four physicians' clerks, for three months; twenty-four surgeons' dressers, for six months; eight ophthalmic and aural surgeons' dressers, for three months; eight gynæcological ward clerks, for three months; eight gynæcological out-patient clerks, for three months; twenty-four assistant physicians' clerks, for three months; twenty-four assistant surgeons' dressers, for three months; forty-eight dressers in the casualty-room, for three months; twelve post-mortem room clerks, for three months.

There are appointments open to students in other medical institutions in the town, and also in the West Riding Lunatic Asylum.

UNIVERSITY COLLEGE, LIVERPOOL, MEDICAL FACULTY: VICTORIA UNIVERSITY.—The Infirmary attached to the School contains 300 beds, with 40 special beds for the treatment of Diseases of Women. Lock, Lying-in, and Eye and Ear Hospitals are in the immediate vicinity, and their practice is open to the students of the Medical Faculty.

The composition fee for lectures and classes is £23 14s. for Preliminary Scientific Classes, and 60 guineas for the Medical Classes required for Victoria and London degrees; 55 guineas for the classes for the London diploma, or 50 guineas without Chemistry. The composition fees are payable in two instalments, with an interval of twelve months. The fee for hospital practice is 40 guineas, which may be paid in the same way.

Two house physicians and three house surgeons are appointed from the qualified pupils every six months, also clinical clerks, dressers, and post-mortem clerks.

Two Holt Tutorial Scholarships, each of the value of £100, are awarded annually by the Medical Faculty to senior students. Also an entrance Lyon Jones Scholarship of £21 for two years for students proceeding to the Victoria degree, and another of the same value open to all students

Digitized by Google

who have completed their second year. The Derby Exhibition of £15 for Clinical Medicine and Surgery. The Torr and School Gold Medals for Anatomy and Physiology, and the class prizes.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, a great extension of the school buildings has been made. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following scholarships and prizes are open to students of the medical school:—A Dauntesey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any medical school in the United Kingdom, and whose age does not then exceed twenty-five years. The subjects of examination are—(*a*) General and Comparative Anatomy; (*b*) Physiological Botany; (*c*) Chemistry; (*d*) Mathematics or Latin. Prizes are awarded at the end of each academic year to students of the first, second, and third year. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the Physiological Laboratory of Owens College, has prosecuted the best original investigation in Physiology, and has passed a satisfactory examination in Physiology. Two Platt Exhibitions of the value of £15 each, to be competed for by first and second year students in the class of Physiology. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. The Turner Medical Prize of £25 is awarded. Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY (300 beds).—Consulting Physicians: Drs. R. F. Ainsworth, Frank Renaud, H. Browne, Sir Wm. Roberts, Henry Simpson, and John E. Morgan. Consulting Surgeons: Mr. George Bowring and Mr. E. Lund. Physicians: Drs. D. J. Leech, J. Dreschfeld, James Ross, and Graham Steell. Assistant Physicians: Drs. Thomas Harris and J. S. Bury. Obstetric Physician: Dr. Lloyd Roberts. Surgeons: Messrs. F. A. Heath, Walter Whitehead, Thomas Jones, and James Hardie. Assistant Surgeons: Messrs. Fred. A. Southam and G. A. Wright. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Resident Medical Officer: Dr. Ernest S. Reynolds. Resident Surgical Officer: Mr. E. T. Milner. Medical Registrar: Dr. R T. Williamson. Surgical Registrar: Mr. W. Thorburn. Pathological Registrar: Dr. R. B. Wild. Assistant Medical Officers: Drs. Isaac Blore and Joseph Clegg. Administrator of Anæsthetics: Mr. Alexander Wilson. General Superintendent and Secretary: Mr. W. L. Saunder.

BARNES CONVALESCENT HOME, Cheadle, Cheshire (in connexion with the Manchester Royal Infirmary; 136 beds).—Resident Medical Officer: Dr. Alexander Johnston. Secretary: Mr. W. L. Saunder.

MONSALL FEVER HOSPITAL, Newton Heath (in connexion with the Manchester Royal Infirmary; 306 beds).—Resident Medical Officer: Dr. H. Falconer Oldham. Assistant Medical Officer: Mr. R. O. Bowman. Secretary: Mr. W. L. Saunder.

RADCLIFFE INFIRMARY, OXFORD.—This infirmary is open to students for Medical and Surgical work in the wards and out-patients' departments. Clinical lectures are given by the Lichfield Clinical Lecturers in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis, and Surgical Manipulation. Practical Pharmacy is taught in the Infirmary Dispensary. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination or the 1st Oxford M.B.

SHEFFIELD SCHOOL OF MEDICINE.—The infirmary contains 200 beds, a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. The Public Hospital and Dispensary contains 101 beds, and is recognised by the examining bodies. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. A tutor's fee of £2 2*s.* is required from students entering for Anatomy and Physiology.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and in case of need are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the hospital, and be supplied with cases of midwifery.

ENGLISH PROVINCIAL HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.

BATH ROYAL UNITED HOSPITAL (120 beds).—Honorary Consulting Physician: Dr. Coates. Honorary Physicians: Drs. Goodridge, Cole, and Fox. Honorary Surgeons: Messrs. Stockwell, Fowler, and Freeman. Honorary Assistant Medical Officers for Out-patients: Dr. Field, Mr. Cowan, and Mr. Craddock. Honorary Assistant Surgeons: Messrs. Green, Scott, and Ransford. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Culliford-Hopkins. The hospital is recognised by the Royal College of Physicians, Surgeons, &c., and licensed for dissections. It contains a library and an excellent museum, in which are a large number of interesting specimens, both in Pathology and Comparative Anatomy. Fees for attendance: twelve months, £10 10*s.*; six months, £5 5*s.* (Temporary pupils can also, by permission of the Honorary Staff, attend the practice of the hospital by the payment of £1 1*s.* for each month.) Instruction in Practical Pharmacy for three months, £3 3*s.* Number of patients admitted during the past year, 1004; out-patients, 7879. Operations performed, 130. Anæsthetics recorded, 115. For further particulars apply to the Registrar and Curator.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. Lewis Shapter, H. Davy, and Arthur G. Blomfield. Consulting Surgeons: Messrs. A. J. Cumming and T. W. Caird. Surgeons: Messrs. Bankart, Harris, Domville, and Bell. House Surgeon: Dr. Russell Coombe. Assistant House Surgeon: Mr. Reginald Martyn. The hospital contains 218 beds (including special children's wards). There is a good library, museum, dissecting and post-mortem rooms. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. For further particulars as to fees &c., apply to the House Surgeon.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Surgical Staff: Messrs. Bankart and Toswill. Registrar: Mr. Roper. The infirmary contains fifty beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1888, 1852. Total number of patients since the opening of the Infirmary in 1808, 73,656.

GENERAL KENT AND CANTERBURY HOSPITAL.—Opened for the reception of patients April 26th, 1793. 51,118 in-patients and 91,585 out-patients have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society, for £7 7*s.* Operation day, Thursday, 11 A.M. Consulting Physician: Dr. Alfred Lochee. Physician: Dr. Henry Alex. Gogarthy. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Charles Holttum, Frank Wacher, T. Whitehead Reid, and John Greasley. Dentist: Mr. Martin L. Bell. House Surgeon: Mr. Z.

Digitized by Google

Prentice. Assistant House Surgeon and Dispenser: Mr. W. F. A. Clowes. Secretary: Mr. Charles H. Read. Over 800 in-patients, 3000 out-patients, and 1000 dental cases are attended in a year.

LIVERPOOL NORTHERN HOSPITAL (150 beds).—There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee. Consulting Surgeons: Mr. W. H. Manifold; Dr. Henry Lowndes; Dr. W. Macfie Campbell. Physicians: Dr. E. H. Dickinson, M.A.; Dr. James Barr. Surgeons: Messrs. Chauncy Puzey, Damer Harrisson, and G. Gibson Hamilton. Fees for hospital attendance: perpetual, £26 5*s.*; one year, £10 10*s.*; six months, £7 7*s.*; three months, £4 4*s.*; Practical Pharmacy, £2 2*s.* Students can enter to the medical or the surgical practice separately on payment of half the above fees.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Paul, Rawdon, and Alexander. Pathologist and Clinical Tutor: Mr. C. J. Macalister. Senior House Surgeon: Mr. W. C. Helme. Junior House Surgeons: Messrs. W. H. C. Davey and W. B. Paterson. There are 200 beds. Clinical Lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships are open to all students. Special wards for accidents and diseases of children. Resident students received.

NORFOLK AND NORWICH HOSPITAL (220 beds).—One year's attendance recognised by the examining boards. Fees: For the physicians' practice, 5 guineas for six months; £10 10*s.* perpetual. For the surgeons' practice, including dresserships, £10 for three months; £15 for six months; £20 for one year; £30 for two years; £40 perpetual. Pupils resident and non-resident. Consulting Physician: Sir P. Eade, M.D. Consulting Surgeon: Mr. T. W. Crosse, F.R.C.S. Physicians: Dr. Barton, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Williams, and Dr. Beverley. Assistant Surgeons: Mr. H. S. Robinson and Mr. S. H. Burton. House Surgeon: Mr. H. Chester Nance. Secretary: Mr. Howard J. Collins.

NORTHAMPTON GENERAL INFIRMARY (Established 1743; rebuilt 1793).—In-patients, 1693; out-patients, 8223. The number of beds is 160. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica and Practical Pharmacy. Pupils' fee £25 per annum, or a perpetual fee of £50.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 200 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 1690; out-patients, 9603. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians and Medical Officers: Dr. J. T. Arlidge and Messrs. M. Ashwell and J. G. U. West. Surgeons: Messrs. W. H. Folker, J. Alcock, and W. D. Spanton. Dental Surgeon: Mr. W. Bartlett. House Physician: Mr. A. Knight Holt. House Surgeon: Mr. A. S. Barling. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees &c. may be obtained.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL (founded 1848; beds, 230).—A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at 11 o'clock, and practitioners are welcomed.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including 28 for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the Dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. Assistant Surgeon: Mr. Joseph Collier. During 1888 there were 1344 in-patients and 10,468 out-patients under treatment at the Dispensary.

SCOTTISH MEDICAL SCHOOLS.

The following schools provide a more or less complete curriculum of medical study.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other Universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other Medical and Public Boards. In accordance with the Statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be attended in this school, each of which *anni medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for any class, taken for graduation in Edinburgh, shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this School.

Fees.—For a first course of lectures, £3 5*s.*; for a second, £2 4*s.*; perpetual, £5 5*s.* To those who have already attended a first course in Edinburgh the perpetual fee is £2 4*s.* Practical Anatomy (six months' course), £3 3*s.*; course of demonstrations, £2 2*s.*; perpetual, £4 4*s.* Practical Anatomy, with course of demonstrations, £4 4*s.* Practical Chemistry, £3 3*s.* Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy, Diseases of the Ear, Diseases of the Skin, Diseases of Children, and Diseases of the Tropics and Climatology, each £2 2*s.* Vaccination, £1 1*s.* For summer courses of Clinical Surgery and Clinical Medicine, each £2 4*s.*; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Practical Medicine and Medical Diagnosis, each £2 2*s.* Insanity, £1 1*s.*

EDINBURGH SCHOOL OF MEDICINE AND PHARMACY, Marshall-street, Nicolson-square.—The classes of this School will be resumed for the winter session on October 1st next. Chemistry, Theoretical and Practical, Midwifery, Surgery, and Medicine. From the Dispensary attached to this institution, Pharmacy, Practical and Theoretical. Practical Midwifery. Out-door Practice. Medical and Surgical Diagnosis. Attendance at this institution qualifies for the University of Edinburgh and all other licensing boards. Tutorial classes in all the branches of the medical curriculum. Preliminary Medical Classes, 11 A.M. to 4 P.M., and in the evening. Particulars of R. Urquhart, Secretary.

ANDERSON'S COLLEGE MEDICAL SCHOOL, GLASGOW.—The following courses are given, which qualify for all the licensing boards:—In winter: Anatomy, Chemistry, Physiology, Surgery, Medicine, Materia Medica, Midwifery and Diseases of Children, &c. In summer: Anatomy, Practical Chemistry, Practical Physiology, Diseases of Women, Medical Jurisprudence, Botany, Hygiene, &c. The Chemical Laboratory is open daily from 10 to 5. Students of the School are admitted to the Lectures and Clinique at the Ophthalmic Institution free of charge.

Fees.—Each course of lectures (except Anatomy), first session, £2 2*s.*; second session, £1 1*s.*; afterwards free. Anatomy (including dissecting-room), first session, £4 4*s.*; second session, £4 4*s.*; third session, £1 1*s.*; summer (including Practical Anatomy), £2 2*s.* Practical Anatomy only, £1 1*s.*; Osteology, £1 11*s.* 6*d.* Students who have attended classes at other schools will be admitted to such classes as they may have attended elsewhere at the reduced fees. Fees for all the Lectures and Hospital practice required of candidates for triple qualification, about £48.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within *two* minutes' walk of it, and *four* minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Physiology, Practical Pharmacy, Operative Surgery and Hygiene, and Public Health. There are also provided a large library and reading-room, and a students' recreation room. The Professor of Anatomy is assisted by four Demonstrators and three Assistant Demonstrators.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The Medical School, which has been carried on for the last fourteen years at the Glasgow Royal Infirmary has been absorbed by, and is to be continued as, the Medical Faculty in St. Mungo's College. This College was incorporated in the spring of the present year. Its objects are not limited to Medicine, but embrace Law, Science, and

Digitized by Google

Arts. Both the Medical and Law Faculties will commence work at the beginning of the present winter session. The Medical Faculty, by arrangement with the managers of the infirmary, who have a representation of nine on the College governing body, will obtain possession of the buildings belonging to them, in which are suitable laboratories, museums, and lecture-rooms, fully equipped for the purposes of a medical college. The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 582 beds, and it has special wards for Diseases peculiar to Women, for Venereal Diseases, Erysipelas, Burns, and Diseases of the Throat. At the Dispensary, special advice and treatment are given in Diseases of the Eye, Ear, Teeth, and Skin, in addition to the large and varied number of ordinary medical and surgical cases—over 40,000 per annum—which in a great industrial centre daily require attention. Students of the College and Hospital get the benefit of dispensary experience free of charge. All appointments are open. There are four Physicians and six Surgeons' Assistants, who board in the hospital, and act in the capacity of House Physicians and House Surgeons. These appointments are made for six months, and are open to students who have completed their curriculum and passed all their examinations except the last, or to gentlemen who have a legal qualification in Medicine or Surgery, to whom preference will be given. Clerks and Dressers are appointed by the visiting Physicians and Surgeons. From the large number of cases of acute disease and accidents of varied character received into this hospital, these appointments are numerous, and valuable to students. In the Pathological Department Assistants are also appointed by the Pathologist. The session will open on Wednesday, Oct. 23rd, at the College buildings.

The fee for each class is £2 2*s*., except for Anatomy, which is £4 4*s*.; but the governors have arranged a sessional fee, payment of which entitles the student to attendance not only on the curriculum classes, but all the classes—nearly as many more as the curriculum classes,—and this sessional fee is only slightly greater than the sum total of the fees required for the curriculum classes. Students are strongly recommended to begin their course on the sessional fee plan. Students who have already taken part of their course at this School, or in other schools, can learn, on application to the Secretary, what in their case the sessional fee would be.

GLASGOW WESTERN MEDICAL SCHOOL.—The School is situated close to the University and Western Infirmary, in which latter students obtain their Hospital Practice and Clinical Lectures. Lectures and Demonstrations are given on Surgery, by Dr. D. N. Knox; on Practice of Physic, by Dr. D. C. McVail; on Midwifery and Gynæcology, by Dr. J. K. Kelly; on Diseases of the Ear, Throat, and Nose, by Dr. Walker-Downie; on Diseases of the Eye, by Dr. F. Fergus; and on Public Health, by Dr. P. C. Smith.

The Lectures qualify for the University of Glasgow, in accordance with the regulations, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of Lectures, except in the special courses, the fee for the first session is £2 2*s*., second session £1 1*s*. Students who have attended a first course elsewhere pay £1 1*s*. For the following three special courses, the fee for each is £1 1*s*.: Diseases of the Ear, Throat, and Nose, Diseases of the Eye, and Public Health.

UNIVERSITY COLLEGE, DUNDEE.—The courses of Lectures and Practical Classes in Chemistry, Natural History, Botany, and Anatomy are recognised for graduation in Medicine by the University Court of the University of Edinburgh. The first year of medical study can thus be overtaken at University College. In accordance with the statutes of all the Scottish Universities, another *annus medicus* can be taken in Dundee by means of attendance during the winter session on Practical Anatomy, and on the Medical and Surgical Practice of the Royal Infirmary.

Fees.—Chemistry: Professor Percy Frankland, Ph.D., B.Sc., &c.; lectures, £4 4*s*.; practical class, winter, £3 3*s*.; summer, £2 2*s*. Anatomy: Professor Paterson, M.D., M.R.C.S., &c.; lectures, £3 3*s*.; practical class, winter, £3 3*s*.; summer, £2 2*s*.; demonstrations and tutorial class, £1 1*s*. Natural History: Professor D'Arcy W. Thompson, B.A., £3 3*s*. (including practical class). Botany: Professor Patrick Geddes, £3 3*s*. (including practical class). Operative Surgery: Dr. MacEwan, £2 2*s*.

Royal Infirmary.—The Infirmary contains 250 beds. There is a special ward for the treatment of children. In addition, during last year there were 3790 out-patients and 5893 home patients. Appointments: Two qualified resident medical assistants are appointed annually; clinical clerks and dressers will be attached to the physicians and surgeons. Students may also be appointed to assist in the post-mortem room. Fee, £2 2*s*. per annum.

Royal Asylum.—Appointments: a qualified resident assistant and resident clinical clerk. Clinical instruction is given at the asylum.

SCOTTISH ANCILLARY SCHOOLS OF MEDICINE.

The following hospitals provide instruction in special branches of medical education and facilities for clinical study:—

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, also to cases of Incidental Delirium or Insanity. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s*.; six months, £4 4*s*.; three months, £2 2*s*.; monthly, £1 1*s*. Separate payments amounting to £12 12*s*. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the pathological department are appointed by the pathologists.

EDINBURGH EYE, EAR, AND THROAT INFIRMARY, 6, Cambridge-street, Lothian-road. Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays and Saturdays at 12 noon for out-door Ear Patients; and Tuesdays and Fridays at 4 P.M. for out-door Throat Patients. Those whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell, F.R.C.S. Surgeons: Dr. J. J. Kirk Duncanson, Dr. G. Hunter Mackenzie, Mr. J. Maxwell Ross, and Dr. William George Sym. Treasurer and Secretary: Mr. A. P. Purves, 12, Queen-street.

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, at 2 P.M., by Dr. Barr and assistants; and operations and special demonstrations to students and practitioners take place on Thursdays from 3 to 4 P.M.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Cutaneous Affections. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students may attend whichever they select at the beginning of the session. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, and extends through the winter and following summer; these are likewise recognised by the University for graduation.

Digitized by Google

Eight resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year; for six months, 7 guineas; and for three months, 4 guineas.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow, situated at Garnet-hill. This hospital was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 70 beds for non-infectious cases only. A specially designed Dispensary, or Out-patient Department, was opened in October last.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street. (40 beds.)—Clinical and systematic course of lectures for students during the winter and summer seasons. In-patients, 481; out- or dispensary patients, 3254. Operations on Wednesdays and Saturdays. Consulting Physician: Samuel J. Moore, Esq., M.D. Acting Surgeon: J. R. Wolfe, Esq., M.D., F.R.C.S.Ed. Acting Physician: J. S. Cumming, Esq., M.D. Assistant Surgeons: J. M'Gregor Robertson, M.A., M.B., C.M., and A. T. Thomson, M.D.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains about 580 beds. Medical Superintendent: Dr. William Reid. Consulting Physician: Dr. Robert Jamieson. Secretary: Mr. W. Carnie. Clinical instruction is given to students during three months in summer.

ABERDEEN ROYAL INFIRMARY.—Contains about 250 beds. Consulting Physician: Dr. A. Harvey. Physicians; Drs. J. W. F. Smith-Shand, R. Beveridge, Angus Fraser, and P. B. Smith. Surgeons: Messrs. A. Ogston, J. O. Will, R. J. Garden, and J. Hall. Ophthalmic Surgeon: Mr. J. McKenzie Davidson. Pathologist: Mr. David James Hamilton. Dental Surgeon: Mr. Williamson. Treasurer and Secretary: Mr. W. Carnie.

IRISH SCHOOLS OF MEDICINE.

LEDWICH SCHOOL OF SURGERY AND MEDICINE, Peter-street, Dublin (formerly original School of Anatomy, Medicine, and Surgery).—There are endowments in favour of students, subject to conditions prescribed by the founder, in the following departments:—Two in Anatomy and Physiology; two in Minute Anatomy; two in Practical Anatomy; one in Surgery. Certificates of attendance on these lectures are received by the various examining boards; by the Apothecaries' Halls of Dublin and London; by the King and Queen's College of Physicians in Ireland; by the Royal Colleges of Physicians, London and Edinburgh; by the Royal University, the Universities of Dublin, London, and Glasgow; by the Glasgow Faculty of Physicians and Surgeons; and by the Queen's University in Ireland. The Senate of the Royal University having recognised the lectures of this School, arrangements have been made to educate students for its Medical and Surgical Degrees in accordance with its requirements. This School is in a central situation, and is replete with every convenience for study and successful instruction. By its teachers it is connected with nine hospitals, four of which are Medical and Surgical hospitals, one for Fever, one for Midwifery and Diseases of Women and Children, one for Diseases of the Eye and Ear, &c.

Returns for the session 1889-90 have not been received from this School.

CARMICHAEL COLLEGE, Aungier-street, Dublin.—The following scholarships &c. are awarded to Students entering for an *annus medicus* for the current year:—The Carmichael Scholarship, value £15; the Maine Scholarship, value £15; also Lecture Prizes, value £3 and £2 each; £97 being given annually in prizes.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Eight Junior Scholarships have been founded in the Faculty of Medicine, of the annual value of £25 each. Two are tenable by Matriculated students, of the first, second, third, and fourth year of their course respectively. The examinations for Junior Scholarships in the Faculty of Medicine take place at the commencement of the session. Matriculated students in Medicine intending to compete for Medical Scholarships of the second year must be of not more than one year's standing as students of Medicine, and must have attended, in some of the Queen's Colleges, or in a University capable of granting degrees in Medicine, two at least of the following courses—viz.: Chemistry, Botany, and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated students in Medicine intending to compete for Medical Scholarships of the third year must be of two years' standing and not more, and must have attended, in some of the Queen's Colleges, or in a University capable of granting degrees in Medicine, four at least of the following courses—viz.: Chemistry, Botany, and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated students in Medicine intending to compet for Medical Scholarships of the fourth year must be of three years' standing and not more, and must, in addition to the qualifications prescribed above, have attended, in their third year, two at least of the following courses—viz.: Theory and Practice of Medicine, Theory and Practice of Surgery, Midwifery, and Diseases of Women and Children.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are awarded every year.

IRISH ANCILLARY MEDICAL SCHOOLS.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months', £8 8*s.* Summer, three months, £5 5*s.*

A resident surgeon is elected yearly, and three resident pupils half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, and in Obstetric Medicine, will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, and Gynæcology.

The certificates of attendance are recognised by all the universities and licensing bodies in the United Kingdom.

COOMBE LYING-IN HOSPITAL, AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN.—The hospital contains 65 beds, and has also a large extern maternity attached. Nearly 3000 confinements are attended annually by the pupils of the hospital. A special dispensary for Diseases peculiar to Women is held daily, and clinical instruction given. The certificates of the hospital are recognised by all licensing bodies, and its diploma is accepted by the Local Government Board, &c. Further particulars can be learned from the Master at the hospital.

SIR PATRICK DUN'S HOSPITAL.—Fees for attendance of students—nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* The hospital is open to extern students as well as to the students of Trinity College, and the certificates are recognised by all the licensing bodies in the kingdom. Dr. Ball, Secretary to the Medical Board, will give any further information.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.—Consulting Physician: Dr. Francis R. Cruise. Physicians: Dr. Christopher J. Nixon, Dr. Joseph M. Redmond, Dr. Michael A. Boyd, Dr. John Murphy. Surgeons: Dr. Patrick J. Hayes, Dr. Charles Coppinger, Dr. Arthur Chance, Dr. John Lentaigne. Obstetric Physician: Dr. Thos. More Madden. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. Daniel Corbett, jun. Pathologist: Mr. Edmond J. McWeeney. House Physician: Dr. Louis Buggy, L.K.Q.C.P., L.R.C.S.I., L.M. House

Digitized by Google

Surgeons: Mr. Wm. R. Morris, M.B., B.Ch., B.A.O.; Mr. John W. Fogarty, M.B., B.Ch., B.A.O. This hospital, the largest in Dublin, at present containing 300 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Instruction at the bedside will be given by the Physicians and Surgeons daily. Clinical Instruction will commence on Tuesday, October 1st, at 9 o'clock A.M. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Thursdays, and Saturdays, at 10 o'clock. Connected with the hospital are extensive Dispensaries which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, &c. Junior Appointments: A House Physician and two House Surgeons will be appointed annually. Eight resident pupils will be elected from the most attentive of the class to hold office for six months. For the current session the election will take place on Friday, Nov. 1st, at 11 o'clock A.M. Dressers and Clinical Clerks will be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes: One Gold and one Silver Medal will be offered for competition annually, in the subject of Medicine, and one Gold and one Silver Medal in the subject of Surgery. They will be awarded on the aggregate of marks gained for Reports of Cases and at a Clinical Examination to be held at the close of the summer session. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Registrar, Surgeon Chance, 15, Westland-row; from the Secretary, Dr. Redmond, 8, Clare-street; or from any of the Physicians or Surgeons.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic diseases.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity in connexion with the hospital, and a dispensary for Diseases peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in midwifery, and lectures on these subjects are delivered regularly throughout the session. Accommodation is provided for a limited number of intern pupils.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 250 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways, and, owing to its position, affords exceptional advantages for clinical instruction. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever Cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, and those peculiar to Women.

The hospital is visited daily at 8.30 A.M. by the resident surgeon, and at 9 A.M. by the physicians and surgeons. The surgical wards are also visited each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants, who, in addition to their rooms and furniture, are provided with coals and gas.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership: £10 10*s.* each three months.

COMPETITIVE EXAMINATION OF CANDIDATES FOR HER MAJESTY'S ARMY, INDIAN AND NAVAL MEDICAL SERVICES.

MEDICINE.

1. A case for commentary having been given, explanation is required of what is meant by (1) "spasm"; (2) "tonic spasm"; (3) "clonic spasm"; (4) "co-ordinated spasm"; (5) "Jacksonian epilepsy"; (6) the method of analysing the convulsive symptoms in this case which point to lesion in a definite region of the brain; (7) define by an ink line on the accompanying brain charts the motor region of the cerebral cortex, and mark with a X on the same chart the probable site of the tumour. [Chart supplied.] 2. Explain the meaning of lithæmia, and nature of the ailment it designates; describe the symptoms and treatment of the condition. 3. Discuss the pathology of typhlitis and perityphilitis as regards:—(1) the origin; (2) the course of these affections. Describe how these conditions are diagnosed from other affections; and lastly, give details as to treatment. 4. Acquired diseases of the heart in children (as distinguished from congenital affections) present certain peculiarities of practical importance. Write what you know regarding these peculiarities as to (1) the parts of the heart involved, and character of the pulse in children; (2) the causes of the lesions and the principles which ought to guide the treatment. 5. Discuss the principles by which you would be guided as to the use of acids or alkalies in the treatment of chronic dyspeptic conditions; and as regards the time for the administration of such remedies.

SURGERY.

1. Describe the symptoms by which syphilitic eruptions may be distinguished from those of a non-syphilitic origin, and the treatment to be adopted in the different varieties of the former. 2. Describe the dislocations common to the elbow joint, the complications which frequently attend them, the modes of reduction, and subsequent treatment of the limb. 3. A patient is the subject of femoral hernia. Describe the symptoms indicative of its becoming strangulated, the operation for its relief, and the general and local after treatment. 4. What are the usual causes of retention of urine in old age, and the best measures for its relief? What subsequent conditions are likely to arise which require the attention of the Surgeon? 5. Describe the symptoms which would indicate fracture of the base of the skull, and the treatment to be pursued under the varying circumstances of such an injury. 6. A patient is the subject of a punctured wound in the groin, attended by arterial hæmorrhage, what treatment should be adopted in such a case?

ANATOMY AND PHYSIOLOGY.

1. Describe the fibula, the origin and insertion of muscles connected with it, and the ligaments which enter into the formation of the ankle-joint. 2. Describe the origin, course, distribution, and anatomical relations of the great sciatic nerve. 3. Describe the small intestine from the pylorus to the ileo-cæcal valve, giving an account of its structure, anatomical relations, vascular supply, and innervation; as also of its functions and the processes carried on in different portions of the length of the tube. 4. Describe the parotid and submaxillary glands, giving an account of their anatomical relations, structural innervation, and blood-supply, the functions they perform, and the chemical and physiological character of the fluid they secrete. 5. Describe the dissection by which you would expose the subclavian artery, mentioning the parts of importance which would be also exposed, and their anatomical relations.

NATURAL SCIENCE

ZOOLOGY.

1. Enumerate in their order from without inwards the fundamental germinal layers of the vertebrate embryo. Which of these gives origin to the brain and spinal cord, and which to the vascular system? 2. What is meant by a water vascular system? Name one or more examples of its occurrence in the animal kingdom. 3. Name the animal defined by the following characters: Notocord persistent; spinal cord not presenting at its anterior extremity a distinct brain; respiratory organ in the form of a dilated pharyngeal sac; the place of the heart taken by pulsatile vascular trunks.

BOTANY.

4. By what anatomical characters may such flowerless plants as present a distinct stem and foliage be divided into two main groups? Give one or more examples of each of these groups. 5. What phenomenon in the life of plants admits of the closest comparison with the respiration of animals? 6. Refer to its natural order a plant with the following characters, and give one or more examples: Corolla gamopetalous, with the lobes imbricate in æstivation, bilabiate; calyx with five, more or less, united sepals, persistent; stamens inserted on the tube of the corolla, didynamous; ovary, superior two-celled, with the placentæ in the axis; fruit, a two-valved capsule; seeds numerous, albuminous.

PHYSICS.

7. A stone dropped into a well strikes the water at the end of three seconds, at what depth in feet is the surface of the water from the mouth of the well? 8. At what angle must a ray of light be incident on a plane reflecting surface in order that the reflected ray be at right angles with the incident ray? 9. To what degrees of Fahrenheit's thermometer do the following degrees of the centigrade respectively belong: 100°, 96°, 29°.

OCIETY of APOTHECARIES, LOND.	....	£4 4 0	....	L.S.A., £6 6s.	
ROYAL COLLEGE of SURGEONS, IRELAND, and APOTHECARIES' HALL, DUBLIN.	....	£12 12 0	£7 7 0 and for Third Professional Examination, £7 7 0	L.R.C.S. Irel., L.A.H. Dub., £7 7s.	

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY.

THE following list is as nearly complete as the Editors have been able to make it, and gives such prizes as would enter into a Student's calculation of the cost of Medical education. It does not contain prizes of less value than £10, or prizes of greater than this value which are given in any form except money or necessaries of medical study and research :—

INSTITUTION.	TITLE OF SCHOLARSHIP &C.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
OXFORD UNIVERSITY ..	....	£80 per annum.	4 years.	Competitive Examination.	....
	Radcliffe Trav. Fellowship.	£200 ,, ,,	3 years.	Ditto.	Foreign Travel for purpose of Medical Study.
	Rolleston Prize.	....	....	Original Research.	
LONDON UNIVERSITY ..	....	£40 per annum.	2 years.	By first place with distinction in ANATOMY at July Intermediate M.B. Examination.	M.B. taken within 3 years.
		£40 per annum.	2 years.	By first place, with distinction in PHYSIOLOGY AND HISTOLOGY at July Intermediate M.B. Examination.	Ditto.
		£30 per annum.	2 years.	By first place with distinction in ORGANIC CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
		£30 per annum.	2 years.	By first place with distinction in MATERIA MEDICA and PHARMACEUTICAL CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
	University Scholarship in Medicine.	£50 per annum.	2 years.	By first place with distinction in MEDICINE at M.B. Honours Examination.	Ditto.
	University Scholarship in Obstetric Medicine.	£30 per annum.	2 years.	By first place with distinction in OBSTETRIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Forensic Medicine.	£30 per annum.	2 years.	By first place with distinction in FORENSIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Surgery.	£50 per annum.	2 years.	By first place with distinction in B.S. Honours Examination.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
EDINBURGH UNIVERSITY	Syme Surgical Fellowship.	£105 16s. 6d. per annum.	2 years	Competitive Thesis by M.B. of not more than three years' standing.	None.
	Leckie Mactier Fellowship.	£70 per annum.	3 years.	Competitive Examination among M.B.'s of not more than three years' standing.	
	Sibbald Scholarship.	£40 per annum.	3 years.	Competitive Examination among University Students.	None.
	Hope Prize.	£25.	....	Distinction in MINOR CHEMICAL CLASS.	None.
	Vans Dunlop Scholarship.				
	,, No. 1.	£100.	3 years.	First place in MEDICAL PRELIMINARY EXAMINATION.	None.
	,, No. 2.	£100.	3 years.	Highest marks in Class Examinations in PHYSIOLOGY and SURGERY.	None.
	,, No. 3.	£100.	3 years.	Competitive Examination in ANATOMY, PHYSIOLOGY, MATERIA MEDICA, and PATHOLOGY.	One year's study at the University, and 2 years' original research.
	Murchison Memorial Scholarship.	Interest on £1000.	1 year.	Competitive Examination in CLINICAL MEDICINE among registered Students of Medicine.	None.
	Buchanan Scholarship.	Interest on £1000.	1 year.	Competitive Examination and Class Work in MIDWIFERY and GYNÆCOLOGY.	None.
	James Scott Scholarship.	£45 per annum.	1 year.	Competitive Examination and Class Work in MIDWIFERY.	None.
	Ettles Scholarship in Medicine.	£20.	....	Distinction in M.B. and M.S. Examination.	None.
	Mackay Smith Scholarship in Chemistry.	£25 per annum.	2 years.	Competitive Examination in CHEMISTRY among University Students.	None.
	Sibbald Bursary.				
	,, No. 1.	£30.	....	....	....
	,, No. 2.	£30.	....	....	....
	Heriot Bursary.				
	,, No. 1.	£30 per annum.	3 years.	Competitive Examination among Matriculating Students.	None.
	,, No. 2.	£30 per annum.	3 years.	Ditto.	None.
	Thomson Bursary.				
	,, No. 1.	£25 per annum.	4 years.	Distinction in Preliminary Medical Examination.	None.
	,, No. 2.	£25 per annum.	4 years.	Distinction in Preliminary Medical Examination.	None.
	Grierson Bursary.				
	,, No. 1.	£20 per annum.	1 year.	Distinction in Preliminary Medical Examination. (Holder must be native of Crawford or Leadhills.)	None.
	,, No. 2.	£20 per annum.	1 year.	Competitive Examination in CHEMISTRY, BOTANY, and NATURAL HISTORY among Second-year Students. (Holder must be native of Crawford or Leadhills.)	None.
	,, No. 3.	£20 per annum.	1 year.	Ditto.	None.
	,, No. 4.	£20 per annum.	1 year.	Competitive Examination in ANATOMY and PHYSIOLOGY among Third-year Students. (Holder must be native of Crawford or Leadhills.)	None.
	,, No. 5.	£20 per annum.	1 year.	Competitive Examination in MATERIA MEDICA and PATHOLOGY among Fourth-year Students. (Holder must be native of Crawford or Leadhills.)	....
	Dr. J. A. Carlyle Bursary.				
	,, No. 1.	£28 per annum.	1 year.	Proficiency in Class Examinations in ANATOMY and CHEMISTRY.	None.
	,, No. 2.	£28 per annum.	1 year.	Proficiency in Class Examinations in ANATOMY and PHYSIOLOGY.	None.
	Mackenzie Bursary.				
	, No. 1.	£21 5s.	....	Industry and Skill in Junior Class work of PRACTICAL ANATOMY.	None.
	,, No. 2.	£21 5s.	....	Industry and Skill in Senior Class work of PRACTICAL ANATOMY.	None.
	Beaney Prize.	£37 10s.	....	Highest Marks taken in ANATOMY, SURGERY, and CLINICAL SURGERY, by University Student in M.B. and C.M. Examinations.	None.
	Hope Chemistry Prize.	£100.	....	Competitive Examination among University Students.	None.
	Neil Arnott Prize.	£42.	....	Distinction in Natural Philosophy in the M.A. Examination.	None.
	Wightman Prize.	£10 10s.	....	Competitive Reports on Cases by Clinical Students.	None.
ST. BARTHOLOMEW'S MEDICAL SCHOOL	Entrance Scholarships No 1.	£65.	....	Open Competitive Examination in PHYSICS and CHEMISTRY.	Full Course at St Bartholomew's Hospital.
	, No. 2.	£65.	....	Open Competitive Examination in BIOLOGY and PHYSIOLOGY.	Ditto.
	,, No. 3.	£130.	....	Open Competitive Examination in PHYSICS, CHEMISTRY, and BIOLOGY.	Ditto.
	Preliminary Scientific Exhibition.	£50[1]	....	Open Competitive Examination in PHYSICS, CHEMISTRY, and BIOLOGY.	Ditto.
	Jeaffreson Exhibition.	£20.	....	Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, FRENCH, or GERMAN.	None.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP &C.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
ST. GEORGE'S HOSPITAL—*continued.*	General Proficiency Prizes. No. 2.	£10 10s.	....	Competitive Examination among Second-year Students in ANATOMY, PHYSIOLOGY, and PHYSIOLOGICAL CHEMISTRY.	
	,, No. 3.	£10 10s.	....	Competitive Examination among Third-year Students in the PRINCIPLES and PRACTICE of MEDICINE and SURGERY, PATHOLOGY, and MIDWIFERY.	None.
GUY'S HOSPITAL..	Entrance Scholarships. No. 1.	£105.	....	Open Competitive Examination among Candidates under twenty years of age in LATIN, GREEK, FRENCH, GERMAN, ARITHMETIC, EUCLID, and ALGEBRA.	Course at Guy's Hospital.
	,, No. 2.	£52 10s.	....	Under twenty-five years of age, ditto.	Ditto.
	,, No. 3.	£131 5s.	....	Open Competitive Examination among Candidates under twenty-five years of age in INORGANIC CHEMISTRY, GENERAL BIOLOGY, and EXPERIMENTAL PHYSICS.	Perpetual Course at Guy's Hospital.
	Arthur Durham Prize.	£15	....	Dissection done by Students of more than one year's standing.	
		£50.		Competitive Examination among First-year Students in ANATOMY OF BONES, LIGAMENTS, and MUSCLES, PHYSIOLOGY, and CHEMISTRY.	None.
		£25.		Ditto.	Ditto.
		£25.		Competitive Examination among Second-year Students in ANATOMY, PHYSIOLOGY, and MATERIA MEDICA.	Ditto.
		£10.		Ditto.	Ditto.
	Michael Harris Prize.	£10.		Competitive Examination among Second-year Students in HUMAN ANATOMY.	Ditto.
	Sands Cox Scholarship.	£15 per annum.	3 years.	Competitive Examination among Second-year Students in PHYSIOLOGY, HISTOLOGY, and PHYSIOLOGICAL CHEMISTRY.	Course at Guy's Hospital.
		£25.		Competitive Examination among Third-year Students in ANATOMY (Medical and Surgical), DIAGNOSIS, OPERATIVE and MINOR SURGERY, MIDWIFERY, and THERAPEUTICS.	None.
		£10.		Ditto.	Ditto.
		£25.		Competitive Examination among Fourth-year Students in MEDICINE, SURGERY, DISEASES OF WOMEN, and MEDICAL JURISPRUDENCE.	None.
		£10.		Ditto.	Ditto.
	Golding Bird Prize.	£20 and Medal.		Competitive Examination among Fourth-year Students in DIAGNOSIS.	Ditto.
	Gurney Hoare Prize.	£25.		ORIGINAL REPORTS on Three Medical and Three Surgical Cases.	None.
	Beaney Prize.	£31 10s.		Competitive Examination among Students in PATHOLOGY.	Ditto.
KING'S COLLEGE	Warneford Scholarships. No. 1.	£25 per annum.	3 years.	Competitive Examination among Matriculated Medical Students in DIVINITY, ENGLISH, HISTORY, LATIN, GREEK, FRENCH, GERMAN, and MATHEMATICS.	Perpetual Course at King's College.
	,, No. 2.	£25 per annum.	3 years.	Ditto.	Ditto.
	,, No. 3.	£25 per annum.	2 years.	Ditto.	Ditto.
	,, No. 4.	£25 per annum.	2 years.	Ditto.	Ditto.
	,, No. 5.	£25 per annum.	2 years.	Ditto.	Ditto.
	,, No. 6.	£25 per annum.	2 years.	Competitive Examination among Matriculated Medical Students in the third year.	
	Sambrooke Exhibitions. No. 1.	£60.	....	Competitive Examination among Matriculated Students in MATHEMATICS, ELEMENTARY PHYSICS, INORGANIC CHEMISTRY, BOTANY, and ZOOLOGY.	Course either as Science or Medical Student at King's College.
	,, No. 2.	£40.	....	Ditto.	Ditto.
	Rabbeth Scholarship.	£20.	....	Competitive Examination among Matriculated Students in Science.	None.
	Science Exhibitions. No. 1.	£50 per annum.	2 years.	Competitive Examination among Candidates under nineteen years of age in MATHEMATICS, MECHANICS, PHYSICS, &c., or alternative Subjects.	None.
	,, No. 2.	£25 per annum.	2 years.	Ditto.	None
	Medical Scholarships. No. 1.	£40 per annum.	2 years.	Competitive Examination among Third- and Fourth-year Students	
	,, No. 2.	£30 per annum.	1 year.	Competitive Examination among Second- and Third-year Students.	
	,, No. 3.	£20 per annum.	1 year.	Competitive Examination among First-year Medical Students.	
	,, No. 4.	£20 per annum.	1 year.	Ditto.	
	,, No. 5.	£20 per annum.	1 year.	Ditto.	
	Sambrooke Registrarship. No. 1.	£50.	1 year.	Competitive Examination among Matriculated Medical Students who have filled certain appointments at hospitals.	
	,, No. 2.	£50.	....	Ditto.	
	Daniel Scholarship.	£20 per annum.	2 years.	Open Competitive Examination among six months' Laboratory Students.

CHANGES IN THE MEDICAL SCHOOLS.

DURING the past year there have been few changes in the constitution of the working staffs of the various London hospitals, while there have been some deaths amongst those on the consulting staffs. Guy's Hospital has suffered in this respect more than the others, having lost Dr. G. Owen Rees, cousulting physician, Dr. Habershon, a former physician, and Dr. Wooldridge, an assistant physician; the vacancy thus caused in the assistant staff was filled by the appointment of Dr. Shaw. St. Mary's has lost its senior consulting physician, Dr. Chambers; Middlesex a consulting physician, Dr. Headlam Greenhow; Westminster a consulting physician, Dr. C. B. Radcliffe. Dr. Gowers has resigned at University College Hospital, and Dr. Bradford has been appointed on the assistant staff. Dr. Gamgee, Assistant Physician to St. George's, has also resigned, and has been succeeded by Dr. Penrose. Dr. Hebb has been appointed Assistant Physician to Westminster Hospital. Mr. Henry Smith was succeeded on his resignation as Surgeon to King's College Hospital by Mr. Rose, and Mr. Penny was appointed Assistant Surgeon, but resigned later, Mr. Carless succeeding him.

At *St. Bartholomew's Hospital* there have been various changes in the lecturers. Mr. Savory resigned the lectureship in Surgery at the close of the last session, and Messrs. Willett and Howard Marsh have been appointed Joint Lecturers on this subject. Mr. Walsham and Mr. Bruce Clarke are the new lecturers on Anatomy, instead of Messrs. Langton and Howard Marsh. Mr. Bowlby takes the subject of Practical Surgery, and Mr. D'Arcy Power that of Surgical Pathology; these gentlemen also conduct the course of Practical Surgery during the summer session, instead of Messrs. Butlin and Walsham. Mr. Lockwood takes the class in Operative Surgery during the Summer. Dr. Herringham has been appointed one of the Anatomical Demonstrators, and Dr. Lewis Jones will share with Dr. Harris the Demonstrations in Practical Physiology.

At *Charing Cross* there have been no changes in the medical staff. In the school some new lectures have been commenced, those on Surgical Pathology to be given by Mr. Morgan, on Therapeutics by Dr. Bruce, and on Public Health by Mr. Heaton. Mr. Boyd takes charge of the classes on Practical Surgery and Operative Surgery, Mr. Pearce giving demonstrations in Practical Pharmacy instead of Mr. Sandall. Messrs. Wallis and Woolett have been appointed Demonstrators in Anatomy.

At *St. George's Hospital*, Dr. Penrose has been elected Assistant Physician in the vacancy caused by the resignation of Dr. Gamgee. Mr. Rideal lectures on Chemistry in the Winter Session, and takes the course on Practical Chemistry in the summer. Mr. Lancaster has been appointed a Demonstrator in Anatomy.

Guy's Hospital has suffered loss in the deaths of a consulting physician—Dr. G. Owen Rees; an assistant physician—Dr. Leonard Wooldridge, who was also a lecturer on Physiology; and one who, though formerly a physician and at the time of his decease holding no appointment at the hospital, was ever a sincere friend to Guy's—Dr. Habershon. The vacancy caused by the death of Dr. Wooldridge has been filled by the appointment of Dr. Lauriston Shaw, who becomes one of the Demonstrators in Pathology and Morbid Anatomy. Mr. Davies-Colley has become Joint Lecturer on Surgery with Mr. Howse, in the place of Mr. Durham; and is succeeded as Joint Lecturer in Anatomy by Mr. Jacobson. Mr. Golding Bird lectures on Physiology, the practical demonstrations during the summer session being given by Messrs. Starling and Tubby. Mr. Symonds conducts the classes in Operative Surgery, and is joined by Mr. Lane in the course of Practical Surgery. These gentlemen also conduct the Surgical classes. The lectures on Biology are shared with Mr. Beddard by Mr. Campbell. Mr. Targett has been appointed a Demonstrator of Anatomy in the place of Mr. Poland. It will also be recollected that this school has added a special Dental to its other teaching departments.

At *King's College Hospital*, a vacancy occurred on the surgical side, owing to the resignation of Mr. Henry Smith, who was made Consulting Surgeon to the hospital and Emeritus Professor of Surgery. Mr. Rose was appointed Surgeon, and the vacancy caused in the assistant staff filled up by the appointment of Mr. W. J. Penny. A new professorial post has been instituted (that of Neuro-pathology), and Dr. Ferrier has accepted the responsibilities of the chair; and Dr. W. R. Smith has been appointed to the chair of Forensic Medicine, vacated by Dr. Ferrier. Mr. Carless has been appointed Assistant Surgeon in the place of Mr. W. J. Penny (who has gone to Bristol), and assists Mr. Barrow in the course on Practical Surgery. Mr. A. S. Underwood has been appointed Dental Surgeon and Lecturer on Dental Surgery. Dr. Dalton shares with Dr. Duffin the lectures on Pathology and Morbid Anatomy, and is also Demonstrator of Morbid Histology and Practical Pathology. Mr. W. K. Dale has been appointed Demonstrator of Bacteriology. Mr. Webb gives practical teaching in Vaccination.

At the *London Hospital* Mr. C. Mansell Moullin has been appointed Surgeon to Out-patients, otherwise there have been no changes. No one has been nominated to fill the post of Lecturer on Materia Medica and Therapeutics, vacant by the resignation of Dr. James.

St. Mary's Hospital.—With the exception of the recent death of Dr. Thomas King Chambers, senior consulting physician, there have been no changes either in the constitution of the visiting staff or the appointments of lecturers. A new out-patient department for children has been instituted, to which Dr. Phillips and Mr. Owen are Physician and Surgeon respectively. Mr. J. J. Clarke has been appointed Curator of the Museum, and Mr. Roughton, one of the Senior Demonstrators of Anatomy. Mr. Herbert W. Page has been appointed Dean of the School in the place of Mr. Field, resigned; the office of Sub-dean has been abolished, and in place thereof a School Secretary has been appointed.

Middlesex Hospital.—This hospital has to mourn the loss of Dr. Headlam Greenhow, consulting physician, whose death took place on Dec. 22nd of last year. Dr. Edis has resigned the posts of Obstetric Physician and Lecturer on Midwifery, and has been succeeded in these by Dr. William Duncan. Dr. Robert Boxall has been appointed Assistant Obstetric Physician and Lecturer on Practical Midwifery. Dr. Wynter has been appointed Medical Registrar in succession to Dr. W. Pasteur, and to him has been given the charge of the Electrical Department. Mr. Carwardine has been appointed Third Demonstrator in Anatomy, in the place of Mr. Vickery. Mr. Laurie takes charge of a class in Advanced Physiology, and Mr. Bland Sutton of one in Morphology for the higher examinations.

At *St. Thomas's Hospital* there have been no changes in the medical staff. Much regret is felt at the departure of Mr. Sidney Plowman for Australia. He was a very popular lecturer, and succeeded in making the subjects of Materia Medica and Practical Pharmacy interesting, as was proved by the large attendance at his lectures. Dr. Hadden and Dr. Acland have been appointed Medical Tutors, and will hold classes weekly.

At *University College Hospital*, Dr. Gowers has resigned the appointment of Physician and been made a Consulting Physician. Professor V. Horsley will lecture on General Pathology as well as on Pathological Anatomy. Mr. Bilton Pollard returns to the Anatomical Department as a Demonstrator with Professor Thane.

Digitized by Google

At *Westminster Hospital*, the consulting staff has lost one of its physicians, Dr. C. B. Radcliffe. Dr. Hebb has been appointed Assistant Physician. Dr. Mercier succeeds Dr. Sutherland as Lecturer on Mental Diseases. In the course on Practical Surgery, Mr. Davy will be assisted by Messrs. Stonham and Spencer.

At *Birmingham* (Queen's College), Mr. Claye succeeds Dr. Bassett in the lectureship on Midwifery, and Mr. Lawson Tait lectures on Gynæcology.

At *Bristol*, Mr. Penny has returned as surgeon to the General Hospital, and takes charge of the class in Operative Surgery in the Medical School, where Dr. Williams has followed Mr. Whishaw as Demonstrator in Anatomy.

At *Cambridge* there have been no changes either in the medical staff of Addenbrooke's Hospital or in the University lectures.

At *Leeds* there are no changes.

At *Newcastle-on-Tyne*, Mr. Williamson has been appointed surgeon in succession to Mr. Armstrong, and Mr. J. R. Morrison to the vacancy on the assistant staff. At the University of Durham School of Medicine, Dr. Howden lectures on Anatomy and takes charge of the Anatomical department.

There are no changes in the *Sheffield School of Medicine*.

At *University College* (Liverpool), Mr. Leigh succeeds Mr. Larkin as Demonstrator in Practical Physiology, and Dr. Thomas has been appointed Demonstrator in Anatomy.

At *Owens College* (Victoria University) *School of Medicine* Professor Hare now occupies the chair in Surgery and also takes the course in Operative Surgery. Mr. Brooke takes the new department of Dermatology. Mr. Smith has been appointed a Demonstrator in Anatomy. Mr. Tanner takes a class in Dental Mechanics, and Mr. Hooton one in Dental Anatomy.

At the *University of Edinburgh* there have been no changes.

At the *Edinburgh School of Medicine*, Dr. A. Bruce takes the entire course in General Pathology. Dr. Gibson has succeeded Dr. James as a Lecturer on Medicine. Dr. Stockman becomes Joint Lecturer with Dr. Craig on the subject of Materia Medica. In the department of Midwifery and Diseases of Women Drs. Bell and Milne Murray are joined by Drs. Matheson, Young, Brewis, and H. Croom; while Messrs. Avison, Rymer, Paterson, and Aitken strengthen the department of Practical Chemistry. Mr. Morrison lectures on Natural History.

At the *University of Aberdeen*, Professor Struthers has resigned the chair in Anatomy, and the vacancy thus created has not yet been filled. Dr. Blaikie Smith is recognised as a teacher in Clinical Medicine. Dr. McWilliam takes the course in Histology, and Mr. Carnelley that in Practical Chemistry. At the *Aberdeen Royal Infirmary*, Dr. Hall has been elected Assistant Surgeon, and Dr. McK. Davidson, Assistant Surgeon in the Ophthalmic Department.

Glasgow.—At Anderson's College Medical School, Dr. W. L. Reid has succeeded Dr. Wallace as Lecturer in Midwifery and Diseases of Women. Mr. J. R. Watson has been appointed Lecturer on Chemistry in place of Dr. Dittmar, and conducts the course of Practical Chemistry during the summer session.——At the Western Medical School in Glasgow, Dr. Kelly succeeds Dr. Reid in the Lectureship on Midwifery and the Diseases of Women. Dr. P. C. Smith lectures on Medical Jurisprudence.

At *Dublin University*, Mr. Macna has been appointed Lecturer on Midwifery and the Diseases of Women. There is no change in the appointments at the Royal College of Surgeons, Dublin, and the same statement applies to the appointments in the Ledwich School of Surgery and Medicine.

At the *Carmichael College* (Dublin), Dr. Macan takes the lectures on Midwifery and the Diseases of Women. Dr. Tichborne lectures on Practical Chemistry (assisted by Dr. Piel), also on General Chemistry. Messrs. Barton, Acock, Craig, McAulay, Graves, Drury, and Grandy are appointed Demonstrators in the Anatomical Department.

There is no change in the *Dublin Catholic University*.

At *Queen's College*, Belfast, Dr. Campbell succeeds Dr. Sinclair in the department of Practical Anatomy; and Dr. Sinclair has been appointed Lecturer on Surgery.

At *Queen's College*, Cork, Dr. E. R. Townsend succeeds Dr. D. C. O'Connor in the post of Lecturer on Medicine.

At *Queen's College*, Galway, there is no change.

A TABULAR VIEW OF THE DAYS OF OPENING OF SESSION, AND HOURS OF THE INTRODUCTORY LECTURES

To be delivered at the different Medical Schools.

	Lecturers.		Days and Hours.
St. Bartholomew's Hospital	(No Lecture) ...	Oct.	1st
Charing-cross Hospital	(No Lecture) ...	,,	1st
St. George's Hospital	Dr. T. C. Allbutt	,,	1st 4
Guy's Hospital	(No Lecture) ...	,,	1st
King's College	(No Lecture) ...	,,	1st 4
London Hospital	(No Lecture) ..	,,	1st
St. Mary's Hospital	Dr. Maguire ...	,,	1st 4
Middlesex Hospital	Mr. J. B. Sutton	,,	1st 3
St. Thomas's Hospital	Mr. W. Anderson	,,	1st 3
University College	Mr. R. J. Godlee	,,	1st 4
Westminster Hospital	Dr. P. S. Abraham	,,	2nd 4
Sheffield School of Medicine	Mr. Chas. Atkin	,,	1st 5
St. Mungo's College and Glasgow Royal Infirmary Sch. of Medicine	(No Lecture) ...	,,	23rd
School of Pharmacy of the Pharmaceutical Soc. of Great Britain	Professor Marshall	,,	2nd 8

MEDICAL TEACHERS.

Dr. ALTSCHUL has made Stuttering, Lisping, Falsetto, recent or of long standing, due to Nervousness, &c., irrespective of age or sex (without any mechanical appliances), his special, life-long study. The voice developed and strengthened.—9, Old Bond-street, W.; and at Brighton and Hastings.

Messrs. BAILLY and COATES prepare candidates for Matriculation, and the Preliminary Examinations at Apothecaries' Hall and College of Preceptors. Careful preparation in Theoretical and Practical Chemistry, Physics, Botany, Materia Medica, and Practical Pharmacy for professional examinations. Laboratory fitted with every requisite.—Preliminary Medical School, 30-32, Ludgate-hill, London, E.C.

Mr. J. BECKTON, C.M., prepares candidates for the London Matriculation, Medical and Law Preliminary, University, Local, and other Examinations. Boarders received.—140, Gower-street, W.C.

Mr. A. H. DAWES, 1st B.A. Lond., gives lessons privately, in class or by post, (in preparation for the London Matriculation and Medical Preliminary Examinations.—31, Southampton-street, Strand, W.C.

Mr. JOHN EVANS, M.A. (in co-operation with his son, J. RHYS EVANS, B.A., Lond., B.A. Cantab., Sen. Opt. and late Scholar of Christ's College, Cambridge), prepares candidates for all Examinations.—Queen's-park, Oswestry.

Mr. J. GIBSON, M.A., prepares candidates for the London Matriculation, and Preliminary Medical and Legal Examinations.—Quernmore, Bromley, Kent, and 24, Chancery-lane, E.C. Mr. Gibson brings out directly after each examination a "Guide" containing the questions set at the examination, followed by solutions in full.

Mr. A. ENT. GOOCH, B.A.Lond., prepares for Matriculation and Preliminary Medical Examinations.—33, Alfred-place, Gower-street, W.C.

Dr. CRESSWELL HEWETT prepares for the San. Science Cert, and all Examinations.—50A, Lincoln's-inn-fields, W.C.

Mr. THOMAS LYLE, M.A., F.R.Hist.S., of the London and Dublin Universities, prepares gentlemen, resident and non-resident, or by correspondence, for the various Preliminary Arts Examinations and Matriculation at the London and Cambridge Universities.—Grove House, Shacklewell-lane, London, N.E.

Mr. A. J. MAINWARING, M.A., prepares candidates for all Preliminary Examinations.—115, Edith-road, West Kensington.

Mr. H. SERGEANT, B.A.Lond., holds special classes, morning and evening, for London University Matriculation, the Preliminary Medical Examinations, &c.—University Institute, 192, Euston-road.

Mr. V. BUTLER SMITH assists pupils in reading up for the London Matriculation, and Legal, Medical, and Pharmaceutical Preliminary Examinations.—Polytechnic, 309, Regent-street, W.

Mr. W. H. VERNON, M.P.S., prepares candidates for Medical and Pharmaceutical Preliminary Examinations and Matriculation.—72, Aubert-park, Highbury, N.

Mr. HENRY WAITE prepares pupils for Matriculation, Preliminary Scientific, and the Examinations for Medical Registration of all the licensing bodies.—342, Strand, W.C.

Mr. H. W. WHITE educates Deaf and Dumb Children of the higher classes on the Pure Oral system; also deals with cases of Defective Speech, and has many testimonials from parents.—115, Holland-road, Kensington.

Mr. J. WOODLAND, F.L.S., F.C.S., holds classes and demonstrations in Practical and Theoretical Chemistry, Chemical Physics, Materia Medica, and Pharmacy. These classes are held for candidates for the Primary L.R.C.P. and the M.B. degree of the different Universities, at the Central School of Chemistry.—173, Marylebone-road, N.W.

Mr. W. VAN PRAAGH has made the cure of all Defects of Speech, both acquired and congenital, his special study.—11, Fitzroy-square, W.

Annotations.

"Ne quid nimis."

THE BRITISH ASSOCIATION AT NEWCASTLE-ON-TYNE.

APPEARANCES augur well for a large meeting of the British Association next week at Newcastle. At a meeting of the Hospitality Committee last week, the Mayor in the chair, one of the hon. secretaries, Professor Merivale, reported that over 1000 strangers had signified their intention of being present, and, as the majority of the members do not usually send in their names until the first day, the attendance thus promises to be very large. The first draft programme of the contemplated proceedings has been prepared, and sets forth that there will be eight sectional meetings. These, for the most part, will be held in a convenient group of buildings between the Newcastle College of Medicine and the Durham College of Physical Science, which, it should be remembered, is also in Newcastle. Besides the sectional meetings there will be various evening meetings. The first will take place on Wednesday, the 11th inst., when Sir F. J. Bramwell will resign the chair, and Professor W. H. Flower, president-elect, will assume the presidency and deliver a lecture. On Friday, Sept. 13th, the first evening lecture will be given by Professor W. C. Roberts-Austen on "Hardening and Tempering of Steel." The second evening lecture will be given by Mr. Walter Gardener on Sept. 16th, the subject being "How Plants maintain themselves in the Struggle for Existence." All the evening meetings will be held in St. George's Hall. The concluding general meeting will be held in the College of Physical Science on Wednesday, Sept. 18th, at half-past two o'clock. On Saturday, Sept. 14th, the University of Durham will give an invitation luncheon in the Castle, Durham, which will be followed by Convocation, when degrees will be conferred on several distinguished visitors. Mrs. Newall has consented to allow members to inspect the large refraction telescope made for Alderman Newall. It is the largest instrument of the kind belonging to any private individual, and, having been presented to the University of Cambridge, it will be removed after the meeting. Musical services will be held in Newcastle Cathedral, and a grand choral and orchestral concert in the Town Hall. Besides, Lord Armstrong will invite the Association to his banqueting hall at Jesmond Dene, as he did on its last visit. A large number of works in Newcastle and neighbourhood will be thrown open to visitors, which, as they are now in full manufacturing swing, must be replete with interest. The North of England Microscopical Society will assist at the *soirées*. Messrs. Barkas and Son, the lessees of the Central Exchange Art Gallery, will throw open their very fine exhibition of local art to members. The gallery itself is one of the finest pillared rooms in England. The week will finish up with various well-planned and interesting excursions.

DEATH OF MR. WALTER COULSON.

WE have much regret in having to announce the death of Mr. Walter Coulson, F.R.C.S. Eng., which occurred somewhat suddenly on Friday, the 30th ult., at the age of fifty-five. The following are the principal facts regarding the melancholy event, so far as we have been able to ascertain:—On Wednesday, Aug. 21st, Mr. Coulson, having suffered a long while from chronic rhinitis and exostoses in the external auditory meatus on both sides, underwent cauterisation treatment at the hands of Mr. Lennox Browne, who at the same time removed the uvula. On the Saturday following, Aug. 24th, Mr. Coulson complained of intense pain in the right ear. This became excessive by Sunday night, when the tympanic membrane burst and discharged pus through the external meatus. The pain was referred by Mr. Coulson to the back of the head. No symptoms of mastoiditis presented themselves. On Monday, the 26th, he had a slight rigor, and then commenced the grave nervous symptoms. On Thursday, Aug. 29th, Dr. Hughlings Jackson saw him and found him nearly comatose, hemiparetic, and with a high temperature. Diagnosing cerebral abscess in a preliminary stage, he strongly urged trephining. Mr. Victor Horsley saw Mr. Coulson the same day, two hours later, and found left graduated hemiplegia from the face downwards, conjugate deviation of the head and eyes to the right; diminution of the deep reflexes on the left side, exaggeration of those on the right, temperature ·6° higher on the paralysed side, &c. Mr. Horsley therefore made the diagnosis of suppurative meningitis extending over the motor area. Trephining as an exploratory measure was then resorted to. The temporo-sphenoidal lobe was exposed, and the dura mater opened. Very little clear cerebro-spinal fluid escaped, and the brain bulged, but repeated tappings failed to strike pus anywhere. Trephining over the middle of the fissure of Rolando revealed a large area in which the membranes were infiltrated with pus to the depth of a quarter of an inch, and the brain was softened beneath for a considerable distance. It was clearly impossible to do more, especially in view of the patient's critical condition. During the night Mr. Coulson recovered consciousness so far as to give rational answers to questions, and he evidently understood the conversation in the room. However, the progress of the malady could not of course be arrested. The temperature rose to 104°, pulse to 140, and respiration to 50 per minute, and he died at a few minutes to 5 on Friday afternoon. Mr. Walter Coulson, who was practically the founder of St. Peter's Hospital for Stone, was nephew of the late Mr. William Coulson, Surgeon of St. Mary's Hospital.

IMPORTANCE OF BUSINESS HABITS.

MANY a professional man, be he clergyman, lawyer, or medical practitioner, has had reason to be thankful that he was first of all put into "business," and was thus given some knowledge of accounts and of business habits. On the other hand, how frequently have professional men—men perhaps of great ability and learning—had to deplore the loss of money, of reputation, or of friends, through carelessness and ignorance in matters of business. In the old days of apprenticeship, not by any means the least of the advantages of the early work in the surgery was that the pupil learned to "keep the books." Now, fortunately, the system of charging by the visit, rather than by the number and size of the bottles of medicine ordered, is so general that "keeping the books" need not necessarily be nearly so arduous and complicated a matter as it used to be. Still, if not done accurately, and if the posting of the ledger and the sending out of the accounts be not done regularly, very serious loss and discredit are likely to accrue. The simplest plan, by the way, is to put down all the work done in the visiting-list, and either to jot down the weekly amount after the Sunday column, and post that into the ledger, or to arrange some intelligible system of signs, by combining crosses and letters, or figures, so that the visits, medicines, and other items can simply be counted up at the end of the month or of the attendance, and their number posted in the ledger, the operation there being then chiefly multiplication rather than addition. If, for example, a patient has had 16 visits and 10 medicines, the charge being 2*s.* 6*d.* per visit and 1*s.* 6*d.* per medicine, it is far easier to calculate $16 \times 2s.\ 6d. = £2$, and $10 \times 1s.\ 6d. = 15s.$,

Digitized by Google

total £2 15*s.*, than to add up the daily amounts in a long column, consisting, as they would probably, of items of 2*s.* 6*d.*, 1*s.* 6*d.*, and 4*s.* Again, many an account which ultimately becomes a bad debt would be promptly paid if the practitioner could, when asked about it, take out his visiting-list and satisfy the inquiry of his client.

THE TEACHING OF SANITARY SCIENCE.

THE teaching of subjects relating to the Public Health is now undertaken at several of the medical schools, and students are there prepared for examination for the several diplomas in Sanitary Science and for holding the appointment of medical officer of health. The result of the passing of the Local Government Act has been a considerable increase in the number of candidates for these diplomas, and necessarily the teaching of this branch of professional knowledge has been carried on more actively in the metropolis than heretofore. But for the efficient education of Public Health officials it is very necessary that some effort should be made to combine the teaching in the several schools in some central institution. The difficulty of maintaining a sufficient laboratory and of arranging for a systematic course in a school where only a limited number of students are intending for themselves a public health career must necessarily militate against the efficiency of the teaching. It would be well if some agreement could be come to among the medical schools for the purpose of putting public health education in the metropolis on a better footing.

DEATH OF DR. M. PERRIN.

OUR Paris correspondent writes:—"I regret to have to report the death of Dr. Maurice Perrin, President of the Academy of Medicine. He was an Inspector-General of Health on the retired list, formerly Director of the School of Val-de-Grâce, Principal Medical Officer of the Army of Marshal de Macmahon in 1870, and Commander of the Legion of Honour. Dr. Perrin was a native of Vezelise (Meurthe), and went through his medical studies at Paris. He soon distinguished himself, and was appointed Professor of Operative Surgery and Director of Ophthalmology and Optometry at the Military School of Medicine and of Pharmacy. Dr. Perrin has published, among other works' "The *rôle* of Alcohol and of Anæsthetics in the Organism,' a "Treatise of Surgical Anæsthesia," and a "Treatise of Ophthalmoscopy and of Optometry." Dr. Perrin, who was sixty-three years of age, died on Sunday last at his native town, after a short illness. His funeral took place at Vezelise.

THE UNIVERSITY OF BERLIN AND POOR STUDENTS.

IT is reported that the Senate of the University of Berlin deprecates the substitution of free study for poor students in place of the present system of allowing such to obtain instruction and attend lectures on credit. The Senate believes that such an innovation might make it impossible for the poorer men to matriculate, as they might have too much pride to accept as a gift what they now merely get on credit.

POST-GRADUATE CLASSES IN LONDON.

WE would draw attention to the scheme, of which full details appear in our advertising columns, for establishing a complete course of post-graduate instruction in connexion with some of the hospitals in the metropolis which have no medical schools attached to them. Each of these institutions has already done much to promote the clinical study of the class of disease to which it is devoted. The co-operation of the several staffs in still further extending their sphere of usefulness is a new departure, which will, we trust, be justified in the success of the project. The courses which have been carried on during the past few years at Charing-cross Hospital have shown that there is a demand for such classes; and the present scheme is likely to be attractive to the practitioner.

VARYING CUSTOMS IN PRACTICE.

A GOOD deal of annoyance is sometimes experienced by a practitioner who, when about to take a holiday, omits to explain to his locum tenens a few minor matters regarding the way his practice is worked; for example, the fees for people who come to the surgery, whether medicine is sent or is to be sent for, the vaccination arrangements, &c. In some practices it is usual to visit confinement cases daily for nine days, and to give a bottle or two of medicine, however well they are doing, and however small a fee they pay. In others, "guinea cases" are only given three after-visits, and no medicine is supplied for mother or child without extra charge. "Locums" who forget that they have the latch-key in their pockets until they are in the train sometimes cause their late principals a considerable amount of annoyance.

FOREIGN UNIVERSITY INTELLIGENCE.

Kiel.—The names of Drs. Anschütz of Bonn and Gabriel of Berlin are mentioned for the vacant chair of Chemistry.

Prague (German University).—Dr. Rudolf Ritter Jaksch von Wartenhorst, Extraordinary Professor of Children's Diseases in the University of Graz, has been appointed Professor of Special Medical Pathology and Therapeutics, with charge of the Second Medical Clinic.

Vienna.—Dr. Rudolf Chrobak has been promoted to the second chair of Obstetrics, with charge of the Second Obstetric Clinic.

AT a meeting of Aberdeen University Court, a few days ago, the resignation of Dr. John Struthers as Professor of Anatomy in the University was formally accepted. The Court also acquiesced in Dr. Struthers' petition that the year which he served in Edinburgh as *locum tenens* for a professor there should be reckoned with the period of his tenure of the Aberdeen chair. The Principal and others passed high tributes on Dr. Struthers' long and honourable services in the cause of medical education in connexion with the University.

THE first International Congress of Physiologists will be opened at Basle on Sept. 10th next, and will sit for three days.

SMYRNA and CONSTANTINOPLE are reported to be suffering from an outbreak of febrile disease.

Correspondence.

"Audi alteram partem."

THE M.D. DEGREE OF THE UNIVERSITY OF BRUSSELS.

"F.R.C.S., L.R.C.P. Lond.," writes as follows:—

Having felt the want myself of some definite information about the examination for this degree, I venture to submit the following notes in reference to the style and the questions asked, which will be of use to those who intend to present themselves for examination.

As regards the subjects in the First Doctorate, Pathology is most important, the examination in this subject requiring very complete answers, as it is not sufficient to have a

Digitized by Google

general idea of the microscopic appearances of the morbid tissues. Last time the following questions were asked:—Tænia solium: Describe its life-history and minute structure of head and segments—viz., uterus, testes, penis, and ovaries. Acarus scabei: Give a description of its three stages. Trichnia spiralis: Describe its life-history and stages. Make a sketch of these parasites, showing the shape of their different organs. Describe the structure of sarcomas, also amyloid disease of different organs (these require a very minute description to satisfy the examiner). Draw the shape and describe the process of staining the more important bacilli—such as tubercle, leprosy, &c.; also the structure of tubercle, epithelioma, and carcinoma. For this part of the examination, Green's Pathology is a book worth reading carefully, and also that of Woodhead. Medicine in the first examination is rather stiff, as the examiner requires a complete answer to his question, and he generally keeps to the one question. The questions asked were: What is Hydræmia, and in what diseases is it found? Glycosuria, including volumetric tests for sugar; enteric fever, with symptoms and treatment during the different stages; hæmoptysis, with all the causes and treatment; acute pneumonia, with the physical signs and their value. In Therapeutics, Mitchell Bruce's book will supply all the necessary information. Mental diseases are asked, but only a general idea is required: such as delirium of persecution, with its prognosis; primary symptoms of melancholia and its varieties; amentia, dementia, and acute and chronic mania. The same examiner asked questions on general pathology and physical signs. The First Doctorate is certainly the most difficult, owing to the fact that generally only one question is asked by each examiner and that a very complete answer is required. Out of twelve qualified candidates who presented themselves five were rejected.

In the Second Doctorate, questions were asked on General Midwifery and Gynæcology, such as abortion, placenta prævia, development of ovum and fœtal circulation, puerperal eclampsia, thrombosis, and white leg. In Hygiene, the student was questioned on impurities in air, different kinds of ventilation, carbonic oxide poisoning, impurities in water, with description of the principal tests; bad meat and its detection; atmospheric pressure, with its effect on disease; and on the precautions to be taken in cases of contagious disease. In Forensic Medicine, the questions were classification of hermaphrodites, laws in reference to contagious diseases, vaccination, &c.,—all very commonsense questions. Surgery is a rather exhaustive examination, the questions being on strangulated hernia, including surgical anatomy and different methods of treatment; and on necrosis of bone, its causes, symptoms, pathology, and treatment.

In the Third Doctorate a thorough practical knowledge is required. The cases given in Clinical Surgery at the hospital were as follows:—Oblique inguinal hernia: surgical anatomy of the parts; treatment and different operations for radical cure. Paronychia: on this subject the questions were very exhaustive, the student being questioned in reference to the connexions of the different synovial sheaths, with the pathology of caries and necrosis. Questions relating to a case of severe contusion and sprain of both ankles were asked, and a classification of sprains required. Concussion of the spine was gone into minutely, questions being asked on the symptoms and diagnosis of fracture and dislocation of the vertebræ, and the methods of localising the position of the injury, with their value in such cases. Clinical Medicine was decidedly the stiffest, the cases being rheumatic fever; hypertrophic cirrhosis of liver; obscure case of enteric fever; phthisis, with heart disease; pleurisy, with effusion, &c. The examiner requires a candidate to examine the case in a systematic manner—first by a series of questions to the patient, then by a general examination of all the organs, and finally of the organs affected. The diagnosis must then be given, the condition of the organs explained, and full directions written as regards food, drugs, and general management of the case suitable for the stage which the patient is in. It is difficult to please the examiner unless the case is gone through systematically. In Operative Surgery the candidate has to perform operations, such as the following:—(1) Syme's amputation; resection of portion of clavicle; tie ulnar artery in middle of forearm. (2) Tie femoral in Hunter's canal; removal of fifth metatarsal bone; resection of portion of rib. (3) Tie brachial at bend of elbow; removal of second and third toes together; suturing a cut in lip. (4) Amputation at wrist; tie brachial in first stage; tie radial in upper third. (5) Amputation of arm and through knee-joint. The operations must be done well, and questions are asked on the relations of the arteries. The examination in Anatomy is not purely regional, as one would imagine from the prospectus, as dissections are required to be done neatly, and the student is asked everything about the parts, including muscles with their nervous supply, and the course of the nerves and arteries. The subjects are not injected. The following parts were given: (1) Dissect parts behind external malleolus and sole of foot; (2) dorsum of foot; (3) palm of hand; (4) popliteal space; (5) front of forearm; (6) bend of elbow. Questions were also asked relating to the parts pierced by a needle passing through the eye from before backwards, and the parts and their order passing through the sphenoidal fissure. Obstetrical operations on the mannikin were—craniotomy; application of forceps in different presentations; transverse presentations, with different methods of turning; mechanism of labour in vertex and face presentations; breech presentations, their complications and treatment; treatment of prolapsed funis, with the methods of using the repositor. Numerous instruments were shown at the Maternity Hospital. This part of the examination is not at all difficult to a man accustomed to midwifery practice.

For the First Doctorate four candidates are examined each evening, fifteen minutes being allowed on each of the four subjects. The same applies to the Second Doctorate, but of course with new examiners. In the Third Doctorate there is no fixed time in the clinical examination, the cases being gone into very fully. Most of the examiners understand English, and some of them speak it fluently; but Dr. L. Wharnot, the interpreter, has the happy knack of putting candidates quite at their ease when his services are required, so that there is no necessity for the candidate to understand French. Anyone wishing to do so can take out a course of Operative Surgery in Brussels some days before the examination for a fee of about 3 or 4 guineas. The examinations are open to the public, and anyone can hear the questions and answers of the candidates, so that I have been present with the other candidates throughout the entire examination.

HINTS TO STUDENTS BEGINNING.

To the Editors of THE LANCET.

SIRS,—As so many freshmen will begin their studies shortly, a few hints from a past student may be opportune. Under the existing regulations far too much of the student's time is sacrificed to mere theory, book-knowledge, and listening to a long series of useless class lectures, and the really important practical knowledge necessary for carrying on his future professional work occupies only a very short period towards the close of his curriculum, and even then the instruction imparted at cliniques is one-sided and of only partial benefit. The result is that, after finishing his course and qualifying, the student finds himself *minus* the experience requisite for starting a practice, and is obliged to spend a year or two as assistant with a general medical practitioner, learning the routine duties of private practice, and the manner and tact &c. necessary for conducting it successfully. Owing to this defective system, the average student has to spend about ten years (one for preliminary and five for professional studies, two as assistant, one at continental schools, and one on a ship) to gain a fairly comprehensive knowledge of his profession before settling down to begin his practice. This is felt to be far too long a curriculum, and requires to be reformed by the General Council. Until then every student should make the most of his time by gaining full experience of private practice during his student days. This can be done by the student strenuously endeavouring to reside as a boarder with a physician engaged in private practice in the city where his medical school is situated. A suitable residence cannot be difficult to secure, as at all important educational centres some private physicians can be found willing to receive one or two boarders during each term. Such a student is indeed fortunate; for he will gain a species of knowledge, confidence, experience, and insight into private practice quite unrivalled, and found to be of lasting benefit for guiding him in his future work.

I am, Sirs, yours truly,

Aug. 31st, 1889. EXPERIENTIA DOCET.

Notes, Short Comments, & Answers to Correspondents.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students, we are necessarily compelled to defer the publication of communications on other important subjects. We regret also to be obliged to hold over till next week an article on Hospital Athletics and the list of prize-winners at the various medical schools and hospitals during the past winter and summer sessions.

We tender our best thanks to those gentlemen who have kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based.*

MICRO-ORGANISMS IN SOIL AND WATER.

THE article on the above subject, about which a correspondent inquires, is to be found in Zeitschrift für Hygiene, Band 6, Heft 3 (published by Veit and Co., Leipzig).

Dr. Clibborn (Bridport).—1. Five medical officers and a dispensary assistant.—2. Salaries from £1000 to £180.—3. The Postmaster-General.

A Subscriber.—We cannot see what offence was committed by our correspondent, or for what he is to be prosecuted.

M.D. B.Sc., &c., is referred to an article on the subject in our current number.

POST-PARTUM SUPPRESSION OF URINE.

To the Editors of THE LANCET.

SIRS,—Dr. Bond's case of suppression of urine after parturition reminds me of a precisely similar case which occurred in my practice in London a few years since. The patient was a healthy young married woman in comfortable circumstances, whom I had attended in a previous confinement. The labour was a natural one, but two days afterwards suppression of urine came on, and in spite of everything that could be done death followed in eight or nine days, preceded by symptoms of uræmic poisoning, stupor, and convulsions. There was not the slightest indication of septicæmia. I am, Sirs, yours faithfully,

Northampton, Sept. 1st, 1889. J. HAWKES, M.D.

"AN ULTRA-CENTENARIAN SURGEON."

THE *Patria* of Buenos Ayres affirms that there is now in Bolivia a surgeon, Luca Silva by name, whose age is no less than 129 years. He was born in Cochabamba in 1760, and devoted himself, after graduating in medicine, to the practice of surgery. He rendered important service to his country, when, after the famous manifesto of June 16th, 1809, she entered on her struggle for independence. His treatment of the wounded, particularly his operations on the field of battle, won him high distinction. He also earned signal honour in the combatant ranks. The other day he was brought to the house of Señor Jose Ramallo, President of the Dramatic College of La Paz, and gave a lucid and animated account of the revolution which, begun in 1809, resulted in the emancipation of his country from the Spanish yoke. Our contemporary would add greatly to the interest of its notice of the "ultra-centenarian surgeon" if it had produced some trustworthy details as to his birth and parentage, certified by the public registrar. As it is, the fact of Dr. Silva's having been old enough in 1809 to practise as a duly qualified surgeon argues a longevity little short of one hundred years.

Mr. F. Treves.—Yes, very soon.

HERNIA AS A RESULT OF DIRECT VIOLENCE?

To the Editors of THE LANCET.

SIRS,—I send the following case for the consideration of your readers. D. C——, aged sixty-two, met with an accident by coming in collision with a steam tram while driving. This occurrence took place on July 11th. I saw him on that night, and, with the exception of a severe shaking, could not find anything particularly wrong with him. Three days after the accident he complained of pain in the left groin, which, on examination, I found was caused by a hernia. Now, was this hernia produced by direct violence? I have no idea of the nature of the accident, as the man cannot tell his own story, having been unconscious for some time. A suitable truss soon relieved the rupture. On Aug. 17th I was called again to see the same patient; he told me that "dropsy" had supervened. I examined his left thigh, and found a large quantity of fluid in or about the sheath of the vastus externus. This I ascertained by exploring with a hypodermic syringe. On recent examination I find that the fluid is now absorbed. Can this be called a hydrocele? I am, Sirs, yours truly,

Stamford-hill, N., Sept. 2nd, 1889. J. J. STACK, L.R.C.P.E., &c.

"DIFFUSION OF SMALL-POX BY HOSPITALS."

To the Editors of THE LANCET.

SIRS,—I have to thank you for your notice of my papers on small-pox and tuberculosis in THE LANCET of July 27th, though your reviewer has mistaken me about winds. All that I assumed in that paper was that when the wind was blowing in a contrary direction to the district affected, cases could not well occur in consequence of infection from the hospital. I was well acquainted with Mr. Power's work, and had given a close scrutiny to the meteorological conditions at Oldham, but came to the conclusion that I could make nothing of them, and therefore did not touch on that subject. I am, Sirs, yours truly,

Oldham, Aug. 26th, 1889. JAMES NIVEN.

THE FOOD OF THE CHILDREN OF THE POOR.

To the Editors of THE LANCET.

SIRS,—If your correspondent, "Parish Doctor and M.O.H.," will communicate his address to me, I shall be very pleased to send him a copy of a card I had printed some years ago for distribution among poor people, entitled, "How to Bring Up Children." It might be of some help to him. I am, Sirs, yours faithfully,

Sept. 1st, 1889. JULIUS CÆSAR.

Clinical Lecture
ON
STRICTURE OF THE URETHRA AND ITS TREATMENT.

By WALTER RIVINGTON, B.A., M.B., &c.,
SURGEON TO THE LONDON HOSPITAL, LECTURER ON SURGERY AND TEACHER OF OPERATIVE SURGERY AT LONDON HOSPITAL MEDICAL COLLEGE.

GENTLEMEN,—The wards of a surgeon to a large hospital like ours are seldom destitute of cases of stricture of the urethra, and in the course of a few years he cannot fail to acquire experience of this serious affection in all its various degrees and phases. As there are few surgical diseases whose safe, speedy, and, if possible, pleasant relief is more essential to the welfare and satisfaction of patients and to the credit of the practitioner, I think I may usefully occupy your time by imparting this experience to you. In the present lecture I propose not to take the history of an individual case or individual cases as a peg on which to hang my remarks, but to lay stress on a few points which I regard as of fundamental importance in the treatment of stricture, and which I have often insisted on during my visits to the wards.

My first point is that no pains should be spared by the practitioner, be he student, house-surgeon, or surgeon, to avoid making false passages. This may seem only a special application of the cardinal rule that the first duty of a medical man is to abstain from doing harm to his patients, but I propose to go beyond the mere inculcation of a general maxim by pointing out the way in which its violation may be prevented. The presence of a false passage augments the difficulty of treating a severe case of stricture of the urethra to a degree which it is scarcely possible to exaggerate. However severe a stricture may be, the surgeon will, as a general rule, succeed in passing a fine bougie by perseverance, gentleness, and tact; but if a false passage exists, the bougie can with difficulty be prevented from entering it, and it is often more by good luck than merit that the orifice of the stricture is penetrated. If we disregard the few cases of traumatic stricture, the ordinary history of a case of stricture admitted into the hospital is this. The patient has had gonorrhœa, and generally more than one attack. His stream of urine has been narrowed for some time, but he has been able to pass it fairly, and has not troubled the doctor, or, if he has, he has not submitted to treatment long enough to be cured. He indulges in unusual conviviality, and becomes the subject of retention of urine. Then he applies at the hospital. Perhaps he declines to stay in—only comes for temporary relief,—and the house-surgeon or dresser must resort to the catheter. The strictured part of the urethra being now congested, the passage is closed, and it is impossible to pass a catheter of a fair size, and a No. 1 or 2 silver catheter is tried. The mucous membrane in the neighbourhood of the stricture in its congested state is unduly soft, and consequently the point of the fine catheter readily penetrates it and makes a false passage, although the operator himself may remain unconscious of having used any force. As a catheter cannot be passed, the patient is sent into the wards, an anæsthetic is given, and another and perhaps a prolonged attempt is made to pass the catheter, but without avail. The instrument only enters the false passage and aggravates the mischief, and thus the false passage is established which entails so much subsequent trouble on both the patient and the surgeon, and interferes with the cure of the stricture. False passages are so frequently made in this manner that I do not hesitate to recommend abstention from catheterism, wherever it is practicable to abstain from it, in dealing with retention, and abstention especially from the employment of the finer instruments. If a No. 5 or 6 silver or flexible olivary catheter can be gently passed, well and good; if not, the patient should be taken in, ordered a warm bath, a drop or two of croton oil or a dose of house medicine, and afterwards some tincture of opium or the liquor opii sedativus, whilst warm fomentations are applied to the abdomen. Retention generally yields to these measures within twenty-four hours, and there is no danger of rupture of the bladder from over-distension within that period, or, according to Mr. Hancock, within forty-eight hours from the time of its commencement. If the surgeon is afraid of this accident, he can aspirate the bladder or tap it above the pubes, but the latter measure and puncture per rectum, which was popular some years back, are operations to which I have not had occasion to resort for a long time. No after-trouble has arisen in the few cases in which I have directed the employment of aspiration, although I am bound to mention that abscesses, extravasation of urine, and even rupture of the bladder have followed it or been attributed to it. Notwithstanding these impeachments, I regard aspiration as a valuable aid in exceptional cases of retention. One or two of the other sources of false passages in former years are now, I think, almost exhausted. One was the practice, and the inculcation by teachers of the necessity for the practice, of the *tour de maître* in passing a catheter. An instance of this came within my cognisance when I was a student at the London Hospital Medical College and was attending the lectures of Mr. John Adams, my predecessor in the anatomical chair. Mr. Adams' lectures were distinguished by a terse and graphic style of description, an Abernethian humour, and an application of anatomical facts to surgery, which always secured the attention of his class. One day when he was discoursing on the urethra and its flexures in the dependent posture of the penis, he demonstrated the mode of introducing a silver catheter, and impressed on his hearers the advisability of mastering the turns of the *tour de maître*. At the conclusion of his lecture an attentive auditor resorted to one of the house surgeons with whom he was acquainted and asked to be allowed to practise catheterism. A patient with rather a large prostate, requiring regular catheterism, was assigned to him, and at his first attempt the student triumphantly accomplished the *tour de maître*, but at his second essay he made the final depression of the handle either too soon or too late, and the point of the catheter hitched against the prostate and caused hæmorrhage, which had to be arrested by the pressure of lint round the penis. It happened to be Mr. Adams' visiting day, and, finding his patient *hors de combat*, he had to be informed of the cause of the misadventure. Curiously enough, Mr. Adams was less gratified with the attention of the student to his lecture and adoption of his advice than might have been expected, for he took occasion to observe to those around him that Mr. —— might be a very clever man, but he trusted that he would not pass any more catheters on his cases. A second cause of the diminution of false passages is the more general preference for the flexible instruments now so extensively made and used, but false passages are still so common in severe cases of stricture as to need all the words of caution which I have uttered concerning them. In congestive conditions of the mucous membrane and in children the urethra is readily penetrated, and there are certain parts of the urethra where obstacles to the passage of instruments present themselves. Sir Henry Thompson lays special stress on three spots in the urethra where this hindrance commonly occurs. The first source of obstruction is close to the external meatus, and is constituted by the *lacuna magna;* the second is where the bulb joins the membranous portion, and the canal, from being wide or dilatable, becomes less so; and the third and last is at the neck of the bladder—the so-called "stricture at the neck of the bladder," which does not ever exist, but "which was a household word some years ago." The *lacuna magna* is to be avoided by following the floor of the canal; the narrow membranous portion at the bulb is to be avoided by keeping the point well against its roof; and the same arrangement or the use of the coudée catheter will overcome an obstacle at the neck of the bladder. Whilst agreeing in the main with these observations, I attach more importance to the passage of the urethra through the triangular ligament combined with the narrowing at that spot than to the narrowing itself. Special difficulty sometimes presents itself in children at this point. A sound, a catheter, or a grooved staff, depressed by its own weight below the level of the orifice, is apt to hitch against the urethral wall as it passes through the triangular ligament, and if the instrument be incautiously pushed against the obstruction, instead of being withdrawn slightly and passed in an altered direction, it may penetrate the passage, perhaps without the cognisance of the operator, and glide

Digitized by Google

beneath the urethra and the prostate gland; it may even reach the recto-vesical pouch of peritoneum. The long sounds with large curves of equal thickness as far as the point, and the long staffs which used to be employed for lithotomy in children, where the length of the instrument supplied a dangerous amount of leverage, were particularly liable to occasion false passages. Most surgeons of experience must have noticed this difficulty in passing instruments, especially, but not exclusively, in children, at the site of the triangular ligament. The utmost gentleness, allowing the instrument to find its way almost by its own weight, perhaps the injection of oil into the urethra before using catheters, staffs, or sounds, constitute the best means of overcoming and avoiding obstacles; and whenever obstruction occurs, either at the triangular ligament or in the prostate gland, the greatest assistance may be derived, both in children and in adults, by passing the left forefinger into the rectum and raising the end of the instrument. There is an old man now in the wards with chronic cystitis, in whom this difficulty exists at the site of the triangular ligament. The point of the sound or catheter sinks below the orifice in that structure, and is arrested by it, but when the forefinger is placed in the rectum, and the extremity of the instrument raised, it passes through readily enough. I believe, therefore, that, so far as false passages are concerned, the neighbourhood of the triangular ligament must certainly be regarded as "the dangerous region." Of late years sounds have been greatly improved by shortening and enlarging the beaks, and lithotomy staffs for children have been lopped of their unfair proportions, so that the danger of making false passages has been minimised. Nevertheless, the danger still exists, and any word of caution that can be given to the inexperienced must be opportune. I have sometimes thought that the veru montanum, when swollen, constitutes an obstacle, and that a small instrument may catch in the sinus pocularis. At all events, I have obtained from the post-mortem room a specimen in which a false passage ran beneath the prostatic mucous membrane from a point in front of the veru montanum to the trigone of the bladder.

My second point will be the value of rest in the treatment of stricture. Most strictures present three elements combined in each instance in different proportions. There is the congestive or inflammatory element, shown by the ready bleeding; there is the spasmodic element, shown by the catheter being gripped and held; and there is the organic, organised, or fibrous element. The organic element is the foundation or the fundamental element of a stricture, and it is doubtful whether either of the other elements alone can constitute a stricture. There must, I think, be at all events a tincture of the organic element. Now, for the removal of the congestion and the spasm accompanying an organic stricture after that alcoholic indulgence which is the source of so many injuries and diseases, and without which death might oftener result from the decay of nature only, the use of instruments is not only not necessary, but may be positively detrimental. And this is the justification of rest in the treatment of stricture. The great apostle of rest, Mr. John Hilton, has treated of many parts of the body in his fascinating volume on Rest and Pain, but has said nothing of the application of rest to the treatment of stricture of the urethra. This omission, however, has been supplied by another philosophical surgeon. Recoiling from the mischief and mishaps due to too assiduous instrumentation of the urethra, Mr. Savory advocated a much more prolonged resort to rest in the treatment of stricture than other surgeons have usually either recommended or adopted. Confinement to bed and the exhibition of opium were, if I rightly remember, the main agents by which rest was to be secured. To a considerable extent I agree with Mr. Savory's remarks; for it is an undoubted fact that when patients are admitted into a hospital suffering from stricture which has been aggravated by congestion and spasm, the treatment which Mr. Savory recommended will suffice ordinarily to remove both the congestion and the spasm, and to restore the patient to the condition in which he existed prior to the attack. Rest for a week or a fortnight is very beneficial, and at the end of that period the surgeon may find that he can pass a bougie, perhaps as large as No. 6 or No. 5, with little trouble, and with no danger of making the patient bleed or creating a false passage. Rest is also very advantageous when false passages have been made. I am therefore never in a great hurry to begin catheterism. On the other hand, there are cases of great severity, very tight and narrow strictures after all the congestion and spasm have gone, which will only admit a fine bougie when you have carried rest to its utmost limit short of an inactivity which could not appropriately be designated as masterly. I remember a stricture case, in which the patient died from bladder and kidney mischief not long after admission, in which no instrument could be passed. At the post-mortem examination we found in the membranous portion of the urethra an organic stricture, consisting of a kind of septum, across the urethra, having at one spot the finest pin-hole aperture, and through this the urine had dribbled. In his admirable teaching in the post-mortem room, Dr. Sutton used often to lay it down as a general rule that in cases of stricture in which it has been found impossible to pass a bougie from before backwards the surgeon would have been able to do so from behind forwards, and that this could almost always be done at the necropsy. This is undoubtedly true in many cases. It is the foundation of the plan suggested by Mr. Furneaux Jordan, of cutting into the membranous urethra, or even the bladder, from the rectum, and introducing a flexible bougie from behind forwards. Another operation based on this fact consists in tapping or incising the bladder above the pubes, and passing a catheter from the internal meatus to the stricture as a guide to a perineal incision. This procedure originated with John Hunter, and in recent years has been practised by the late Mr. Callender, and in 1878 by Mr. Howse in a very difficult case of traumatic stricture. My own case was an exception to the rule that an instrument can be passed through so-called impermeable strictures from behind forwards, for not the finest filiform bougie could be passed either from the front or from behind, even when the specimen was removed from the body. In such a case rest till doomsday would not have altered the stricture one iota. By all means, then, employ rest as far as it may avail for the abolition of the congestive and spasmodic elements of a stricture, and for the avoidance and healing of false passages, but when you have reached the limit of forbearance, at once commence the use of instruments in a regular, persevering, and systematic way, for without instrumental aid an organic narrowing cannot be removed.

My third point is the necessity of eclecticism in the use of instruments. For a long period our insular prejudices and preference for silver catheters, made on an irregular scale, prevented surgeons from profiting by the great improvements introduced by the ingenuity of our Gallic neighbours, who were much in advance of us in regard to the treatment of stricture. This state of things was fostered by our ready submission to authority. There is not a body of men existing anywhere who more blindly follow authority than the members of the medical profession, and in this instance authority emanating from University College inculcated the superior value of the silver catheter and metal instruments. Now, however, the scientific pendulum has swung to the opposite side, and it is recognised that everyone who has experienced the passage both of a silver and a soft flexible instrument on his own person will give so decided a preference to the latter that it may be enunciated as an axiom that a metal instrument should never be employed when a soft instrument will suffice. It is not possible always to adhere to one description of catheter. Surgeons of large experience must have met with cases in which it was difficult to pass a flexible instrument, whilst a silver or metal instrument glides in easily; and other cases in which silver or metal instruments may be arrested, whilst flexible instruments are admitted with facility. Then there are cases which seem, indeed, to be cases of stricture, for a small catheter cannot be passed, and the surgeon is told by his house surgeon: "This is a very bad case of stricture, sir; I cannot get in a No. 1 or ½"; and the surgeon takes a full-sized silver catheter and passes it into the bladder without a hitch. These are the kind of cases which have been diagnosed as stricture, and which from some other urinary trouble have reached the post-mortem table, where the cynical pathologist, not without an incompletely veiled note of exultation, after acquainting himself with the diagnosis entered on the ward paper, announces that he cannot find a trace of stricture throughout the urethral tract. The explanations of the three kinds of cases which I have just mentioned comprise such conditions as spasm (and this is a very real condition now and then); slight obstruction, which suffices to arrest a flexible instrument; tortuosity of the canal, which may stop a silver instrument; a slight bar in the prostate, or at the neck of the bladder; large follicles,

Digitized by Google

like the *lacuna magna* and others, which all look towards the meatus, and which are avoided when an instrument is passed from behind forwards, but often hinder the progress of fine bougies and catheters; the narrowing of the urethra at the junction of the bulbous and membranous portions; the passage of the urethra through the triangular ligament; and some difficulty in micturition due to other causes than stricture, but hastily set down as due to stricture itself. The surgeon of experience is alive to all these sources of fallacy, and runs them over in his mind when a difficulty occurs. Hence he almost intuitively adapts his means to the end in view; and it is this superiority in experience and judgment which may enable the older man, perhaps even the old fossil, to cope with the brilliancy of youth, a little too confident in its own opinions and powers. There is a further fallacy, to which Mr. Berkeley Hill has directed attention; and that is, that a narrowing near the meatus may give rise to the semblance of a stricture some inches down; with the division of this narrowed part the suppositious stricture at or near the bulb entirely disappears. Another instance of varying our means is afforded by a simple expedient recommended by authorities in using fine bougies. Our treatment of the tightest strictures consists in endeavouring at first to introduce the finest bougie, and when this is accomplished (*ce n'est que le premier pas qui coûte*) the stricture may almost be regarded in the generality of cases as cured. The bougie is retained and the patient passes urine by the side of it. As soon as the stricture is dilated sufficiently, a bougie or catheter a size larger is passed, and then the French catheters (much superior to the English variety) are resorted to till the full size is attained. Now, in passing a fine bougie, success is much more likely to be secured if it is turned up a few lines from the point. By this means it is lifted from the floor of the urethra or turned away from contact with the urethral wall, and more readily avoids follicles, and enters the orifice of a stricture which may be placed in any position in relation to the circumference of the canal. I have often succeeded by practising this simple manœuvre, when subordinates, not initiated into this trick of the trade, had failed. Larger catheters and bougies also pass more readily when turned up at the point, and the French coudée catheter is one of the most useful instruments, especially for employment by the patient himself, in cases of enlargement of the third lobe of the prostate. When you have selected a filiform bougie, whether flexible or of catgut or whalebone, and bent it up at the point, it is a good plan to inject oil into the urethra. The bougie is then introduced, and a rotatory movement given to it whenever it is arrested, and when it arrives at the stricture. By twirling it round between the finger and thumb as it is pressed onwards, the tip is enabled to enter the strictured part. If it becomes engaged in a lacuna or a false passage, you may either withdraw it a little and then twirl it on again, or leave it there and pass a second, and if this also gets into another lacuna or false passage you may pass a third and repeat the process until all the lacunæ or false passages are filled, when another is passed, and will probably traverse the stricture unless it becomes bent upon itself. Success, however, does not always attend this ingenious method, and I generally prefer persevering with a single filiform bougie. Whalebone is the best material if the stricture resists penetration, but, being stiff, it may make a false passage without proper care. If the stricture admits a filiform bougie the surgeon has open to him more than three courses. He may leave the bougie in for two or three days and thus obtain what may be called physiological dilatation of the stricture. This course I prefer very much to resorting to any variety of physical force, open or disguised. A covert way of applying physical force is to employ tapering bougies, and long ones, with a fine or filiform extremity, are made for this purpose. The objection to this wedge-like pressure is that the stricture resents it, and on removal of the bougie swelling takes place and the canal becomes blocked. A bougie that is left in a stricture ought to pass quite easily through it. If you try to hurry the dilatation of a stricture, you soon find out the truth of the proverb, "The more haste the less speed." *Festina lente*, as Mr. Harrison advises, is an excellent maxim. The wedge-like method of dilatation may be carried out by means of other instruments now before us. There is the American plan of screwing on to the small bougie one of larger size, or a catheter, and pushing forward the small bougie so as to double it up inside the bladder. Either a flexible or a metal instrument may be screwed on to the bougie. Then there is the plan of sliding catheters over the filiform bougie. I will not undertake to say when the sliding principle was first introduced, but Dr. Andrew Buchanan and Mr. T. Wakley introduced instruments of this kind. Here is a very long tube sliding over a bougie which, I am told, is used sometimes by one of my colleagues, and may be applied indifferently to the urethra and the œsophagus. I have not had any experience of it, but I have employed with advantage Gouley's tunneled catheter on the recommendation of Mr. Reginald Harrison. This catheter which I have in my hand is threaded near the point on to this whalebone bougie, which is first introduced into the bladder through the stricture. By exercising a little pressure Gouley's catheter can generally be induced to slide along the bougie through the stricture into the bladder, and seems to me to be the best instrument of the kind for retention cases. Again, Holt's dilator may be screwed on to a filiform bougie, which is pushed before it into the bladder, and rapid dilatation or disruption practised. Holt's dilator has been loudly extolled by some and as loudly condemned by others. It may be employed in one of two ways—either for forcible splitting of the stricture, or quite gently, persuasively, and almost lovingly, after the manner of a glove stretcher. In this latter way the tube is insinuated along its guide, and the stricture sufficiently stretched to permit a larger instrument than before to be introduced. When employed for disruption the tubes are pushed rapidly and forcibly along the guide. Most surgeons, I think, prefer internal urethrotomy to splitting; for splitting, it is said, is not a truly scientific method. The surgeon does not know precisely what he is doing. Not only does he tear through the stricture, but the rent is liable to invade the healthy urethra to an extent which the surgeon can neither regulate nor foresee. The rent is ultimately repaired by fibrous tissue, which contracts, and a bad traumatic stricture is added to the original narrowing. Mr. Teevan used to say that he had a black list of bad cases to bring against the splitting method, whilst the supporters of the plan aver that they never saw any harm result from it. Internally urethrotomy has been equally lauded and condemned. I have used both methods sparingly, and, so far as my experience has gone, with no other than good results. But there are special dangers from all instruments and operations, and occasionally from internal urethrotomy. You may have undue hæmorrhage, extravasation, rigors, and suppression of urine, which will be a set-off against the ill effects sometimes following splitting a stricture. Even simple catheterism has its fever, and, without any fault of the surgeon, may be attended by a fatal issue when the kidneys are unsound.

The last point to which I ask your attention to-day shall be the necessity for an accurate diagnosis of strictures—their size, shape, position, number, and nature. For this purpose we can scarcely dispense with the bulbous instruments which are known as the bougies or sondes à boule, and the bougies or sondes à demi-boule. "The shape of the bullet of an exploring sound best suited to its purpose," says Mr. Berkeley Hill, "is that of a turkey's egg, which is a little more pointed than that of the common hen. The circumference of the big end corresponds to the number of the sound. The bullet is attached to a slender stem no thicker than No. 5 French. When made of flexible material the stem should be marked in inches and half-inches by white rings, the fifth inch from the point having a wider ring than the rest to serve as a landmark. The position of any obstruction can at once be noted by observing how many rings have passed the meatus. Again, the bulb at the end of a slender stem transmits impressions from only that part of the canal against which it is pressed, and as it passes along the canal it is checked by an unyielding point, or gives slight pain to the patient whilst it traverses an inflamed area. Directly the wide bulb has passed these situations of disease and reached a healthy part of the urethra, no sense of resistance is felt and no discomfort experienced by the patient until the bulb arrives at the next diseased locality, because the slender stem does not distend the urethra. Thus the bulb and graduated stem enable the surgeon to ascertain the number, length, and exact position of the indurated or inflamed patches of the urethra. When no stricture is present, no difficulty checks the passage of the bulb to and fro in the urethra if the triangular ligament be not passed. At that point the change of direction and often a slight diminution in calibre

Digitized by Google

of the urethra through the orifice in the anterior layer of the perineal fascia to twenty-seven or twenty-six millimetres usually check and sometimes stop the passage of a bullet bougie, and pain is felt by the patient. But it is seldom, if ever, necessary to pass the triangular ligament to discover unyielding parts of the urethra. Old well-marked strictures do invade the membranous part, it is true; but such have so greatly altered the form of the urethra in front as well as behind the perineal fascia that their detection is easy, and the bullet sound is not needed to discover such indurations." Three sizes of these flexible bullet sounds are generally made, corresponding to about Nos. 8, 12, and 14 or 15 English catheters, or 17, 22, and 25 or 26 French catheters. There are several advantages to be gained from the use of the bougies à boule, which, as Mr. Teevan was constantly insisting, must be distinguished from the bougies olivaires. By their aid you can detect slight and commencing strictures which would be overlooked by the mere use of ordinary flexible or gum-elastic or silver catheters or sounds. If one of these catheters or sounds passes a stricture on entrance without detection, it will pass it on its exit; but a bougie à boule of proper size, if it passes the stricture on entrance, will detect it on withdrawal, for the shoulder catches against the narrowed part owing to the contraction of the urethra behind the bulb of the instrument. A second advantage of the bullet sounds is that you can ascertain the number and exact position of the strictures present. I have used them for the last ten years, and by their means have become acquainted with a fact which I should never have ascertained by the use of tapering or cylindrical sounds or catheters, and that is that urethral stricture is very often multiple. There are generally two, three, and sometimes four strictures in an affected urethra. As these strictures are of different degrees of severity, it is quite easy to overlook all but the worst contraction. There may be a contracted meatus, a narrowing in the glandular portion, a stricture two or three inches down, and a fourth, and perhaps the worst, at or near the bulb. If the less conspicuous narrowings are overlooked, the patient does not not derive the full benefit from treatment, and is more likely to relapse. Thirdly, the bougie à boule is most useful in discovering congested patches in the urethra which will become the site of stricture, and whose presence is the cause of a gleety discharge after local excitement now well recognised as indicative of commencing stricture. The flexible bullet sounds should be made of all sizes on the French scale like Otis's metal bulbs, and I regard them and the Otis urethrometer or expanding bulb as most valuable for the measurement and discovery of pathological narrowing of the urethral canal. On this point, therefore, I cannot agree with the sweeping condemnation passed upon them by Sir Henry Thompson in his excellent Clinical Lectures on Diseases of the Urinary Organs. After advocating for diagnosis the employment of a No. 10 or 11 flexible English gum-elastic bougie slightly curved towards the point with a blunt end (since a tapering point of course will not mark distinctly the site of the stricture), he shows that a stricture will be detected by the bougie "being grasped somewhat as it is withdrawn." He then passes this judgment on the bougie à boule. "Now, with the common exploring instrument, which is formed of a long small flexible bougie, terminated by a bulb of considerable size, nothing is more easy, especially with an unpractised hand, to deceive oneself with respect to the existence of stricture. If not drawn out accurately in the axis of the passage you may feel a check, and readily find what you believe to be a stricture in the most healthy urethra. And that is precisely what I am so anxious to guard you against, for in the hands of designing persons these instruments may be turned to most unworthy purpose. For men outside the ranks of our profession, or holding a questionable position on its outskirts, these instruments are the very things. That is an additional reason why we should be careful not to encourage their unnecessary use. I have for twenty years past used small bulbous instruments in metal for the diagnosis of narrow and confirmed stricture on which it is desirable to operate, but for slight stricture never; and I have protested against their use on the two grounds already named: first, that for such the instrument inflicts needless pain; secondly, that it is liable to deceive a young operator not too adroit or familiar with its use." Neither can I agree even with Mr. Harrison, who thinks that the best instrument for exploration is "the plain bougie, with the end slightly rounded (not bulbous) to facilitate its introduction. If a surgeon cannot by this obtain all the information he requires about the urethra, I am sure," he says, "he will not be assisted by any of the bulb or olive-headed instruments which are vaunted for this purpose. It is a matter of touch and of handling. What is wanted is the *tactus eruditus*, the acquisition of which requires as much practice as is needed to detect fluctuation. To the unpractised hand the whole length of the urethra is a stricture, which no form of instrument renders otherwise." Most unquestionably a practised hand will detect by an educated touch far more than a beginner even with an ordinary sound or catheter; but the practised hand will discover more with a suitable than an unsuitable instrument. And, as regards the bullet sounds, I cannot do better than quote the teaching of a former colleague of Sir Henry Thompson's, who is on the Court of Examiners at the College of Surgeons, and will not therefore, I presume, be regarded either as a designing person, or as outside the ranks of the profession, or holding a questionable position on its outskirts. In November, 1879, in some excellent lectures on stricture of the urethra, published in the *British Medical Journal*, Mr. Berkeley Hill took a view of the comparative diagnostic value of the bougie à boule diametrically opposed to that of Sir Henry Thompson. He then said "the size and shape of the instruments employed in the examination of the urethra are of great importance; indeed, unless you provide yourself with suitable instruments, you will not gain any precise knowledge of the condition of the urethra you are asked to treat, and will probably bungle in your treatment. Bullet sounds with slender stems (sondes à boule), some flexible, some rigid, are requisite in addition to the urethrometer. In searching for stricture I discard instruments with tapering points or of equal calibre throughout—the ordinary so-called French and English bougies or sounds; they are deceptive in several ways. For example, an instrument of which the stem and point are of equal thickness is gripped the whole time it is passing through the stricture, and the presence of other non-expanding points behind the first, notified by the sound, is not perceptible, unless indeed they be narrower than the first, when they stop the further progress of the instrument." With these remarks I fully coincide, and can only add that the fact that a valuable and necessary instrument may be abused is no argument against its legitimate use. If it were, the female speculum, the laryngoscope, and even the clinical thermometer would have to be discarded. As to the disagreement of surgeons in their estimates of surgical procedures and instruments you need not be surprised or troubled, for we constantly find that even within a brief space of time a surgeon will disagreewith himself.

THE INFREQUENCY OF CANCER AMONG FEMALES IN THE ENGLISH LAKE DISTRICT.

BY ALFRED HAVILAND, M.R.C.S.,
LATE LECTURER ON THE GEOGRAPHICAL DISTRIBUTION OF DISEASE AT ST. THOMAS'S HOSPITAL, ETC.

AT a time of the year when the facilities for enjoying one of the most beautiful and interesting districts in England are yet in full career, the readers of THE LANCET may not think inopportune the following notes, made during a recent visit to Kendal, with the view of supplementing my remarks published last year in that journal on some of the causes coincident with the low mortality from cancer among females in the Lake District.[1] As the copies of THE LANCET containing the articles referred to may not be at hand, it will perhaps be well to give a brief summary of the facts connected with the distribution of this disease in Great Britain.

In 1868, in a paper read before the Medical Society of London, illustrated by a large coloured map, I first demonstrated that cancer among females had a well-defined geographical distribution throughout England and Wales, and that when the cancer map was studied in connexion with a geological map of this country the following disease

[1] The Geographical Distribution of Cancerous Disease in the British Isles. THE LANCET, vol. i. 1888, pp. 314, 365, 412, and 465.

Digitized by Google

and geological facts were coincident:—(1) That among the 630 registration districts into which England and Wales are divided, those low-lying districts which were either traversed by, or were contiguous to, fully formed rivers that seasonally flooded the country through which they flow were characterised by the *highest* mortality from this cause of death. (2) That, on the other hand, those districts which had the *lowest* mortality had a high average level, were situated on or near the water-partings where rivers derived their sources, and where the rock-base under their soils consisted of the older geological formations, such as the Cambrian, Silurian, old red sandstone, and mountain limestone, or of the more recent chalk, and where floods were either impossible or only temporary.

Such were the simple facts which I announced nearly twenty-one years ago, based upon the deaths that took place from cancer among females during the ten years 1851–60. Since then I have added the facts which the succeeding ten years (1861–70) have afforded me, gathered from the late lamented Dr. William Farr's second decennial supplement to the late Major Graham's (Registrar-General) thirty-fifth annual report. Owing, however, to the supplement for the last decennial period (1871–80) being defective, the present Registrar-General having incontinently and confusedly mixed up the male with the female deaths, further addition to my twenty years' facts is impossible until this report is amended and published in the form established by Dr. Farr. This defective report is fully discussed in the articles in THE LANCET already mentioned, to which I must refer the reader, only adding that the defects in this perfunctory report have been brought to the notice of the Government, and it is hoped that before long the work will be placed in competent hands, and reissued in accordance with Dr. Farr's models.

The facts of the second decennial period (1861–70) confirming in every respect those which I announced in 1868, and have just briefly repeated, the question then arose, How did river floods affect the local climates of those districts wherein for twenty years cancer proved itself most deadly? In the first place, it was discovered that in some oft-flooded river valleys, such as that of the Thames, remarkable exceptions were to be found—namely, that in four of the riparial districts of this river a comparatively low mortality from cancer among females obtained; two of these districts, Wycombe and Cookham, were above London, and two below, Orsett and Dartford. These districts were found in pairs, one lying on the right and the other on the left bank of the Thames, and separated only by the river. Coincident with the low mortality of these two pairs of districts was the fact that at both these points in the river's course chalk came to the surface and formed the rock base of the soil of these four riparial districts, whilst underlying the gravel and alluvium of all the high-mortality riparial districts were the Oxford clay, the Kimmeridge clay, Gault clay, plastic clay, and London clay, all retentive strata, and calculated, as will be presently seen, to intensify the evils of floods and their sequels—dead vegetation and vegetable decomposition,—resulting in the formation of numerous gases and acids, which not only render the soil sour, but injuriously affect the atmosphere that lies above it, and therefore the local climate of the district where floods occur, and far beyond their high-water mark. It is a well-known fact that by the retention of the acid products of vegetable decomposition consequent on river floods the superficial soil is rendered sour, and the subsequent herbage rank and deleterious, especially to young cattle and sheep. It is also well known that the grass which covers the soil overlying chalk or limestone is sweet, even when these rocks are covered to a considerable depth by sands and gravels, whether of post-glacial or of recent fluviable origin; whereas, when the chalk or limestone underlies a considerable deposit of boulder clay or recent alluvial clay, their neutralising powers are barred from taking effect by the intervening obstructing layer of retentive soil.

It has been shown in my work on the Geographical Distribution of Heart Disease,[2] and in my more recent lecture on the Distribution of the Wheat-yield in Great Britain,[3] how the configuration of the country influences the free access of the prevailing winds; how when access from the sea is aided by the direction of the trend of the valley systems coinciding with that of the atmospheric currents; and how it is obstructed when the river valleys are at right angles to them, in the latter case causing them to blow over instead of up through them, as in the former system. In England and Wales the prevailing winds are either south-westerly or north-easterly. In the case of free and unobstructed access, the valleys are swept clean of all residual air, and are thus purged of atmospheres contaminated either by emanations from the soil or human habitations. On the other hand, when free access is barred, and the winds are forced over the water-partings, all that is deleterious in the atmospheres in the valleys below is rendered still more deleterious by accumulation; hence it is that in such pent-up stuffy valleys the local climates not only engender diseases, but intensify those that are imported into them. Two thousand five hundred years ago Hippocrates pointed out the different effects on health experienced in "stuffy hollows and in fresh uplands." Knowing these facts, it will not be difficult to understand why, in the case of cancer among females, we find those districts where the soil favours the intensification of the evils of floods varying in their death-rates from this cause, according to the configuration of the land in which they lie; in fact, why the more pent-up inland districts should have a higher death-rate, as a rule, than the more open ones, exposed to the free access of the winds and their air-flushings and oxidising properties. With this introduction I will now give a brief account of my late investigations in the English lake district.

At the International Geological Congress held in London in September, 1888, I pointed out to the members the fact above narrated with regard to the coincidence of low mortality in the Thames valley with out-crops of chalk in the districts where it occurred. That the vegetable acids, the result of vegetable decomposition after floods, were neutralised by the chalk I have not the slightest doubt; neither had those around me who were at the time looking across the Thames at the chalk at Purfleet, in the Orsett district, whilst standing on the chalk of the Dartford district, and admiring the chalk flowers that bloomed around us. The soft nature of the rock precluded the permanence of the effects of acid erosion on its surface. Moreover, the permeability of chalk allowed the rain to enter its structure rather than run over it laden with the acids, and etching channels as it flowed. In the harder limestone, however, the acids leave permanent records behind of their having been neutralised by the carbonate of lime.

Whilst visiting Kendal this year, with the view of comparing the limestone of the southern Lake District with that in the Isle of Man, and of studying the relation of these rocks to the fully-formed rivers of this district, through the courtesy of the honorary secretary of the Westmorland Natural History Society, Mr. Severs, I made part of an excursion to the limestone escarpment of Lyth Fell, where are to be seen on a gigantic scale the records of vegetable decomposition and vegetable acid etching of the tilted limestone slabs, on which the dead leaves of the shrubs and trees of the wood had fallen and decayed. The limestone dips at an angle varying from 5° to 20° towards the east, and forms a bold escarpment looking towards the west. The joints are all enlarged by "weathering" and the erosion of the vegetable acids, so that they are often dangerously deep, and remind one of the Chasms in the Isle of Man; the surfaces of the tilted slabs are carved into long, deep, and tortuous watercourses. The upper margins of the slabs are entire, but the lower are eaten through, forming, in fact, the outlets or mouths of the strangely serpentine channels. In each channel lies dead and dying vegetable matter, creating fresh acids for the next rain to wash out of its mass and thus enlarge and deepen the channel in which the mass rests, which in many places completely covers the stone. This "weathering," as it is termed, has been ascribed to rain alone, which, by means of the carbonic acid it contains, is said to dissolve the carbonate of lime by converting it into the soluble bicarbonate; but anyone who at a glance can see scores of acres of tilted slabs all sculptured into serpentine channels as I have described, and these channels filled with decaying acid vegetation, will not find it difficult to understand that the rain finds powerful allies in the sour masses on which it falls in its work of erosion, nor will he hesitate to accept the evidence before him of the power of neutralising the acid products of vegetable decomposition in carbonate of lime in the form either of limestone or of chalk. These limestones have been described

[2] The Geographical Distribution of Heart Disease, Cancer, and Phthisis. Folio. Smith, Elder, and Co., 1875.

by Mr. A. Strahan in his memoir on the Geology around Kendal. "In the Kendal area," he says, "they dip to the east, and present an unusually precipitous and continuous face to the west; on the east they are cut off by a fault. This limestone forms the most northerly projection from a much-faulted range of carboniferous rocks, which fringes the Lake District on its south side." In fact, at and below Kendal as far as Duddon Mouth they underlie the superficial and permeable sands and gravels traversed by all the rivers that fall into Morecambe Bay. Again, on looking at a geological map of this part of England, it will be found that these limestone rocks are continued on the north-east of Kendal at Orton, whence, as the same author remarks, they form part of a prolonged escarpment of these rocks, which fringes the Lake District on its north and east sides. These limestones form a crescentic belt around the Lake District, which can be traced from Duddon Mouth through Kendal, and through out-liers at Skelsmergh and Gray Rigg to Orton, whence it continues in an unbroken line onward by the north to the Whitehaven district. I must, however, remind the reader that whilst in the south, below Kendal, this limestone crescent underlies those parts of the rivers where floods may most frequently occur, and therefore where its influence would be most required, along the remainder of its course by the east and north to Whitehaven it crosses the higher parts of the many rivers which radiate from the central water-parting of the Lake District, consequently where floods are either impossible or rare. These facts should be remembered when the statistics of cancer among females are discussed. The distribution throughout Great Britain of phthisis being so markedly the reverse of that of cancer, it is always instructive to study the two causes of deaths together whenever possible.

The English Lake District.—The seven registration districts that constitute the English Lake District belong to three different counties: (1) Cumberland, including Penrith, which may be said to share Ulleswater with Westmoreland; Cockermouth, in which are Thirlemere, Derwentwater, and Bassenthwaite; Buttermere, Crummock, and Lowes Waters; Whitehaven with Ennerdale, and Bootle with Wastwater. Two belong to (2) Westmoreland West Ward, sharing Ulleswater with Penrith, and containing also Haweswater and Brotherswater; and Kendal, which includes Kentmere, Windermere, and Grasmere. One district belongs (3) to Lancashire — Ulverston, — which includes Coniston-water, and may be said to share Windermere with Kendal. All these lakes average a level of 326 feet above the Ordnance datum.

The Distribution of Cancer and Phthisis in the Lake District compared.—In 1868, in a paper read before the Medical Society of London, I first pointed out the significant fact that throughout England and Wales the distribution of these two diseases greatly differed from each other; so much so, in fact, that the *high* mortality districts in one map were, as a rule, represented by *low* mortality in the other, and that when low mortality from these two causes of death were coincident, the districts were found to be the healthiest, as indicated by their death-rates from "all causes." In 1887, in a lecture delivered at the Edinburgh School of Medicine, embodying the results of recent investigations throughout Scotland, I showed that these diseases had a similar distribution in North Britain. With regard to the Lake District, I have shown that throughout the twenty years 1851–1870 it had a low mortality from cancer among females as the rule. In Great Britain the districts having the highest death-rates from phthisis are invariably those that are most exposed to the full force of prevailing winds, which I have explained in my work on "The Distribution of Heart Disease, Cancer, and Phthisis," and again in the one on "Scarborough." We shall therefore be prepared to find that the most exposed lake districts have a higher death-rate from this cause than the more protected ones. Thus the exposed lake districts are Cockermouth (28·53), Whitehaven (26·54), Bootle (35·88), Ulverston (28·61); the mean annual death-rate from phthisis to every 10,000 females living being 28·61. On the other hand, the sheltered lake districts have a less though still high death-rate: thus, Penrith (26·71), West Ward (25·95), Kendal (28·07), mean, 26·91. When, however, we take the cancer death-rates a great difference is seen. Taking the districts in the same order, the annual death-rates from cancer among females are as follows:—The coastal: Cockermouth (4·58), Whitehaven (2·93), Bootle (3·23), Ulverston (2·88), mean 3·40. Inland: Penrith (5·11), West Ward (4·67), Kendal (3·12), mean 4·30. If we take the mean cancer and phthisis death-rates among females for the seven lake districts during the twenty years 1851-70, we find the following—cancer 3·80, and phthisis 28·38, the latter very high and the former very low, but strictly in accordance with the rule stated above. Again the coastal lake districts have a mean death-rate for cancer of 3·40, and phthisis 29·49, the former below and the latter above the lake standard. Whilst in the inland districts the reverse obtains: the cancer death-rate, although low when compared with that of England and Wales for the same period (4·78), is higher than the local standard (3·80), amounting as it does to 4·30. This, too, is in perfect harmony with what I have taught prevails throughout Great Britain. Of the inland districts Kendal (3·12) was the lowest cancer death-rate, and this agrees with its double character, for, independently of its geological features, which are all in favour of a low cancer death-rate, an important section of its population (55 per cent.) is exposed to the full influence of the prevailing winds from Morecambe Bay, which thoroughly air-flush the lower valley of the Ken and thus keep its local climate free from stagnation and the consequent accumulation of injurious emanations from the soil. Coincident with this free exposure of the lower valley to the full force of the winds from the sea, we find that, whilst it has the lowest death-rate from cancer, it has the highest from phthisis amongst the inland lake districts.

The Increase of Cancer.—In 1886 I read a paper before the Collective Investigation Committee appointed in accordance with the suggestion of the Berlin Medical Congress with the view of reporting upon my works on the distribution of disease, in which I drew attention to the fact that, whilst undoubtedly cancer was increasing and phthisis decreasing in this country, the latter disease had been found to be increasing in some districts where cancer was actually decreasing. In the Lake District cancer has increased very little indeed among females. In the north Lake District it has actually decreased, the death-rate in 1851–1860 being 4·15, whilst in 1861–70 it only amounted to 3·99. In the south Lake District in 1851–60 it was 2·75, but in 1861–70 it rose to 3·63; whilst for the whole of the Lake District the rates were 3·52 for 1851–60, and 3·82 for 1861–70. During the same periods the districts of Cumberland and Westmoreland outside the lakes had a mean death-rate in 1851–60 of 3·63, whilst in 1861–70 it amounted to 5·58. It may therefore be said that, among the female population living within the influence of the English lakes, cancer during the twenty years 1851–70 pursued a steady low course, whilst generally throughout England and Wales it had been increasing in its ravages, and that this increase was evident even in the districts immediately outside the lakes.

There is yet a more certain and useful test of the accuracy of the above statement—namely, the elimination from the mean female populations and the deaths of cancer occurring among them of all women above thirty-five years of age, and of the deaths that took place at and above that age during the twenty years 1851–1870. During those twenty years the mean female population in the Lake District amounted "at all ages" to 98,580, amongst whom 729 died of cancer. At the same time there was a mean population of women living, amounting to 30,757, at and above thirty-five years of age, of whom 693 fell victims to cancer, so that over 95 per cent. (96·06) of the deaths from this cause among females occurred at and above thirty-five years of age.

Now, if we take the annual death-rate from cancer to every 10,000 women living at the above age-period, we shall find that, whilst in England and Wales it amounted to 14·31, in the Lake District it reached only 11·50, equal to an annual saving of 2·81 to every 10,000, which, in round numbers, among the 30,000 women, would equal a saving of 170 lives during the twenty years. In other words, the death-rate in the Lake District being 11·50 instead of 14·31, nearly 20 per cent. (19·63) of valuable lives are saved from succumbing to this terrible cause of death.

When it is proved that a fell disease like cancer claims victims in every district of South and every county of North Britain at an increasing rate, and whilst the natural history of such a long-torturing cause of death is still quite unknown, it is a gain at least to discover where certain conditions of soil and local climate exist that are proved to be coincident from one end of this country to the other, with its least power to torture and destroy; it is satisfactory also

Digitized by Google

to know that the conditions favourable to the lowest form of mortality from cancer are well defined, of certain character, and admit of a simple description and an explanation which appeals to the understanding and common sense of all. To know where those should go or be sent who are threatened with this disease, with the best chance of arresting its development, is a gain in preventive medicine; and it is a relief to know that the most beautiful part of our country—the English lakes—not only possess the conditions of soil and climate found to be the least conducive to the growth of this disease, but that these conditions have during the twenty years taken been effective in keeping it at bay, whilst in other parts, and closely around, cancer has been gaining ground.

I first studied the physical configuration of the Lake District in relation to local climate and disease distribution from Windermere, where every facility for investigating the northern Lake District is at hand during the season. During my last investigation I selected Kendal as the centre, and found it an admirable station, the neighbourhood being full of interest for the naturalist, the archæologist, the geologist, and the medical geographer. The beautiful drive from Kendal over the Windermere Ferry at Bowness, by Esthwaite, Tarn Hawes, through Hawkshead to Coniston-water, and back by Ambleside, Windermere, and Staveley, will give the student a better idea how local climates are formed, and how much they are dependent upon the geological structure and physical configuration of the district, than any written description, especially if he make on his way graphic notes in his sketch-book. From Kendal, too, the limestone country around the rivers which flow into Morecambe Bay can well be studied, as well as the superficial drift deposits, forming *drumlins* of sand and gravel over 300 feet high sometimes, as the Castle Hill. The "Concangium" at Water Crook, south of the town, is highly interesting to the visitor, and has much to tell the medical geographer. This old Roman Castrum, the flocks of gulls that fly around and feed in the river around it, and even the stormy petrels found sometimes in the streets of Kendal, are all regarded with interest by those who study local climates with the view of tracing their connexion with local flora and local diseases.

NEW ANTISEPTIC ARTIFICIAL TYMPANIC MEMBRANE.

BY JOHN WARD COUSINS, M.D. LOND., F.R.C.S.,
SENIOR SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL AND TO THE PORTSMOUTH AND SOUTH HANTS EYE AND EAR INFIRMARY.

THE essential qualities of a good artificial drumhead are numerous. 1. It must, first of all, decidedly improve the hearing power. 2. It must be so constructed that it can be easily placed in the right position and easily removed; it ought also to be especially adapted for self-application. 3. It must be extremely light and delicate in structure, so that it causes no sensation or irritation in the meatus by its presence. 4. The artificial drumhead ought also to be an efficient protector to the injured organ, and a screen for maintaining the moisture of the exposed tympanic cavity. 5. It should be capable of fitting the varying capacity of the external meatus, so that, when once placed in position, it is not liable to displacement. 6. It ought to be a convenient vehicle for the application of local astringent and deodorising remedies. 7. The contrivance should be obtainable at a trifling cost, so that a new artificial membrane may be used as often as necessary.

The new membrane which I desire to submit to the criticism of my professional brethren is represented in Fig. 1. In shape it is exactly like a hat with a very high and tapering crown and a broad and flat brim, having a short ribbon attached to the edge. It is just firm enough in substance to retain its shape in the ear, and yet the material is so soft and flexible that it causes no sensation by its presence. It is stained a delicate flesh colour, and is made in several sizes to suit the varying capacity of the external meatus. When in position the crown rests near the tympanic membrane, the brim upon the meatal wall, and the little ribbon or handle behind the tragus. The method of manufacture has been worked out by a series of experiments. The material is composed of compressed cotton fibre, swollen by prolonged immersion, and saturated in an antiseptic oil and ether. The soft material is then firmly compressed in a little machine that I have designed for the purpose, and afterwards dried by artificial heat.

One marked feature of the new antiseptic membrane is its extreme lightness. The weight varies a little according

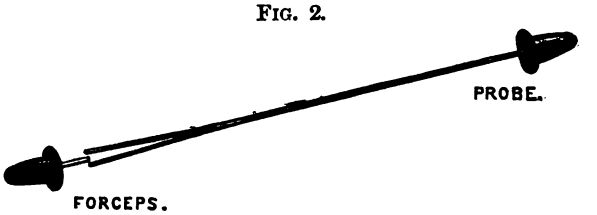

FIG. 1.

to the size, and this has a range from one-sixth to one-quarter of a grain. I have often introduced it without the patient being aware that anything had been put into the meatus.

Another special quality consists in the facility with which it can be introduced and removed by the patient himself. The little instrument for the self-application of the artificial membrane is depicted in Fig. 2. The probe end is

FIG. 2.

inserted into the crown of my little hat, and in this way it can be accurately placed in the meatus, and then detached from the instrument by the aid of the sliding collar. Patients very soon get into the way of adjusting it and slipping it into position, with just the right amount of pressure for securing the best result. The forceps is intended to be used for the removal of the artificial membrane, and in doing this patients are guided by their tactile sensibility. Traction is made upon the handle, which ought always to be easily found resting just behind the tragus.

It is a matter of great practical importance in every case that the artificial membrane should be selected to suit the shape and capacity of the external ear. It is my practice to regulate the height of the crown by the sensations of the patient and the breadth of the brim by the size of the meatus. It must not fit too tightly, but simply rest in contact with the meatal wall, so that after it has been put into the right position it does not get easily displaced. It is not necessary to place the crown upon the perforation or in contact with the remnants of the tympanic membrane. The surgeon cannot select the point of contact by any internal scrutiny of the organ; but, in every case he must be guided by the sensations of the patient and the improvement produced in the hearing power.

The artificial drumhead may be regarded also as an ear protector and a local antiseptic remedy. I have recently made some impregnated with the oils of eucalyptus globulus and pumiline pine in combination with other aromatic substances, and their agreeable fragrance renders them extremely grateful to some patients, especially those who have suffered from offensive discharge. Other patients with perforation of the tympanic membrane, but without serious deafness, have used them as ear protectors with great comfort. In such cases the artificial membrane forms a screen between the middle ear and the external meatus, and acts as an efficient shield during rough and cold weather.

With reference to the length of time an artificial membrane can be retained in the ear, I recommend a fresh one to be introduced every day, and of course this is absolutely necessary in all cases of otorrhœa. It should be taken out

Digitized by Google

during the night, and put in directly after the local treatment is finished in the morning. Some patients make one of the drumheads do for two or three days. A medical friend, who has been using my little hat for several months, informs me that he has often kept one in his ear for a week without removing it. Of course this is a detail which must vary in different cases, and patients soon learn to arrange it for themselves.

The antiseptic artificial membrane does not require to be moistened before introduction. If the passage is dry, it should be wiped out with a weak solution of boracic acid or any deodorising lotion. On two occasions only patients have complained of some temporary irritation from its presence in the meatus. One was a case of gouty eczema of the auricle, and in the other the external ear was particularly tender and irritable from chronic inflammation. Under these circumstances a morsel of lanoline containing cocaine can be used with great relief just before the introduction of the artificial drumhead, and I always direct that the membrane should only be retained for a few hours at a time until the sensibility of the meatus has subsided.

The new antiseptic artificial membrane and aural probe can be obtained from Messrs. Burroughs, Wellcome, and Co., Snow-hill Buildings, E.C., at a very trifling cost.

Southsea.

HAIR PASSED IN THE URINE.

BY WILLIAM O'NEILL, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE LINCOLN LUNATIC HOSPITAL, ETC.

ON May 5th. 1887, I was consulted by Mr. A—— for disease of the bladder, one very remarkable feature of the complaint being that he passed hair in the urine. The patient was fifty years of age, rather short and stout, and regular and temperate in his habits. Twelve months before he called upon me he began to suffer from irritability of the bladder; three months after this he noticed blood in his urine; and about five months subsequently to the hæmorrhage he discovered hairs in that fluid. The hairs at the outset were single and not very numerous; but as time went on they increased in number, and some of them formed little tufts. The patient sometimes felt a sense of weight and uneasiness in the region of the bladder, but he did not seem to have suffered much pain, excepting occasionally when in the acts of micturition the flow of urine was interrupted by clots of blood. The hæmorrhage from its commencement recurred every five or six weeks, but the bleeding was not very profuse at any time. In the attack preceding his calling upon me, he thought, however, that he had lost more blood than on any other previous occasion; nevertheless, he was still a ruddy-faced, healthy-looking man. He had declined in weight, but this he accounted for by recently defective appetite, and from being frequently disturbed in the night by the irritability of the bladder. The patient's urine was abundant, averaging about four quarts a day, but then he indulged in copious draughts of milk, to which he was rather partial. The specific gravity of the urine ranged from eight to ten degrees; the reaction of the urine inclined to alkalinity, and when free from blood it contained merely a trace of albumen, but no renal casts, mucus, or pus. Floating in the urine, or lying on the bottom of the chamber-vessel, now and again could be seen particles of matter which the patient called "skins," and which to my unassisted eye looked like little bits of coagulated albumen or fibrin stained more or less with blood. Also in the urine at all times could be seen hairs, more or less numerous, of various shades of dark and light colour, and varying in length from half an inch to two inches and a half, and I have seen a few hairs not less than four or five inches in length, which he assured me he had drawn out of the urethra. On looking at some of the ordinary hairs that I chanced to have preserved, I find the majority of them are light in colour, and that the thick and thin ends are well marked, even in the most downy specimens. When the urine contained blood, the hairs assisted in forming little clots, which the patient had sometimes difficulty in voiding; indeed, it was this fact that first drew his attention to the hair. As might be supposed, some specimens of urine contained more hair than others. On one occasion I fished out of a chamber-vessel not quite full of urine a small ball of hair. The patient, who was a clever man, frequently looked at the hairs through a microscope, and was familiar with their appearances and peculiarities. I have had the urine microscopically examined by two young medical men, who in addition to the hair only found some blood-corpuscles, epithelial scales, and on one occasion pus-cells. To prevent any extraneous matter finding its way into the urine I ordered the chamber-vessels to be always washed with pure water before the patient passed urine into them, and to be kept closely covered till examination took place. In the carrying out of these commands it was not an uncommon thing to see a row of six or eight vessels arranged along the wall of the patient's bedroom; the arrangement frequently excited a little mirth in some of his relatives, who could not see any use for "such a display of crockery."

I may say that with the exception of the bladder complaint Mr. A—— considered himself in fairly good health. His pulse was regular, his heart and lungs were sound, and there was little or no increase of temperature. On account of the hæmaturia he was ordered gallic acid and hamamelis virginica, and when the hæmorrhage was subdued he took nitric acid, buchu, uva ursi, and strychnine. In this way he went on slightly improving until the sultry weather of August, when he was attacked by most violent diarrhœa and vomiting, and whilst in this state he was suddenly seized with apoplexy, which carried him off in a day or two. I was told that the patient's family is peculiarly susceptible to bowel affections, which in its members generally assume a grave character, for two of his sisters and a brother had died of intestinal diseases of some kind.

In the absence of a post-mortem examination, it is impossible to say what the state of the bladder was that gave origin and growth to the hair which constantly appeared in the patient's urine. It may have been that the hæmorrhage, the hair, and the so-called "skins" came from the same diseased surface, or from a tumour of some sort in the bladder. I have an impression that the blood proceeded from a villous or papillomatous tumour, and that the hairs grew on the mucous membrane, from which they were constantly shed. Hair passed in the urine must be a very rare phenomenon for, on referring to Dr. Neale's "Digest," that valuable work gives only two examples of it—one published in THE LANCET in the year 1860, and the other in the *British and Foreign Medico-Chirurgical Review* for 1874. I regret that on neither of these papers am I able to lay my hands. Infrequent as the disease is, it has been heard of by some of the vendors of quack nostrums. Before I had seen the patient, he had been taking for several months a mixture which an accompanying advertisement stated would cure many and various maladies, and among the rest the disease which caused hairs to grow in the bladder.

Lincoln.

ON THE PATHOLOGY OF RENAL DROPSY.

BY A. G. AULD, M.D.

THE pathology of dropsy, and of renal dropsy in particular, has excited considerable interest and discussion since the experimental inquiry which is chiefly associated with the name of Cohnheim.[1]

With respect to the œdema of hydræmia, Cohnheim, and with him Lichtheim, found in their experiments that a simple hydræmia or even hydræmic plethora was insufficient for its production. It was necessary that a change in the capillary wall of a paralytic nature be superadded, tending in all probability to cause a loosening of the attachments of the endothelial cells of which it is composed. In one experiment, Cohnheim and Lichtheim ligatured the iliac vein of a dog, yet this was not followed by œdema of the corresponding limb. Ranvier repeated the experiment, and in addition divided portions of the sciatic nerve. It was found that while section of the motor fibres of the nerve gave negative results, section of the vaso-motor fibres was followed by œdema of the limb. Salvioli obtained similar effects in dogs rendered artificially hydræmic. With respect also to the lymphatics, it is found that their complete occlusion is, at least for a time, un-

1 Virchow's Archiv, vol. lxix., p. 106: "Ueber Hydrämie und Hydrämisches Œdem."

Digitized by Google

attended by œdema of the pertaining parts. In another experiment Cohnheim depleted a dog, and injected salt solution till hydræmic plethora ensued. The result was a great increase of the natural secretions—e.g., saliva, bile, urine, and intestinal fluid; but not until the hydræmic plethora was of the most extreme kind was any dropsy manifested, and then in the form of ascites only. Not only so, but Fleischer,[2] after tying the ureters and adding urea to the injected liquid, failed to obtain anasarca, nor was the blood pressure permanently raised.

On the strength of these and such-like experiments, Cohnheim came to the conclusion that dropsy occurring in the human subject was caused, not so much by a hydræmia or hydræmic plethora, as by a morbid alteration in the walls of the capillaries favourable to an increased transudation of their fluid contents. This alteration he considered to be due to the direct action of a particular poison existing in the blood, the nature of which is problematical, but defined by some in the case of renal dropsy as the same specific agent which affects the kidney. It is, however, suggested by Brunton[3] that it may be sarco-lactic acid, which, in conditions of imperfect oxygenation, may be formed instead of carbonic acid, he and Cash having discovered that the addition of dilute acids to the blood not only causes increased permeability of the vessels, as observed by Gaskell, but also œdema of the surrounding tissues. In reference to this question, it may be said that, apart from inflammatory conditions, there is but scant evidence to maintain the proposition that the existence, and even the prolonged existence, of a poison in the blood has any direct influence in the production of dropsy. Were it so, this symptom would be much more frequent, and at the same time much less significant, than it really is. Quite an exceptional instance, however, is found in the case of arsenic, which causes an œdema of obscure origin said by Feitelberg[4] to be the outcome of defective oxygenation. It could hardly be justifiable to adduce the malignant œdema of Koch in this connexion, which is due to the action of a bacillus, though Bienstock,[5] indeed, states that a somewhat similar organism can be cultivated from the fæces of man. On the other hand, there can be no doubt whatever that there are poisonous substances which by reason of their deleterious action on the blood act as remote causes in the production of dropsy. This is well illustrated in the case of the œdema of chlorosis, there being every reason to believe that this cachexia is intimately related to the absorption of ptomaines and leucomaines from the stomach and intestinal tract, as declared both on pathological and clinical grounds by Bouchard, Duclos, Sir Andrew Clark,[6] and others.

Again, with respect to the locality of the œdema, it is found in disease, and especially in renal disease, that hydræmic plethora is chiefly associated with symptoms the very reverse of those occurring in Cohnheim's experiment—with œdema, namely, of the skin and superficial tissues of the body, and with a diminution of the natural secretions and excretions. Pathologists have been much troubled over this very decided though instructive contrast, for the explanation of which various opinions have been advanced. Cohnheim himself supposed the skin in renal disease to be in a morbid state, its vessels debilitated, and more susceptible to the action of the poisonous agent which he believed to exist—a condition which, indeed, demonstrably obtains in the case of scarlatinal dropsy. Coats,[7] commenting on this, imagines that a special vulnerability of the skin, is, from its physiological relationship, to be apprehended in kidney disease, and he further considers it probable that it is injured by the same irritant which attacks the kidney. Hamilton,[8] in his search for an explanation, goes almost the length of contradicting himself. He believes the œdema to be induced by a long-continued stretching of the skin, for the production of which there was not sufficient time in the experiments on dogs, and yet elsewhere he states truly that the superficial œdema commences where the tissues are very lax. The most striking negation to the theory that the œdema of the skin is owing to a special participation of this texture in the disease is that afforded by the similarly distributed œdema which results from retention of urine, independently of any renal disease. This curious phenomenon has been particularly investigated and described by Trousseau.[9] Its symptoms consist in an enormous distension of the bladder, with frequent or continuous dribbling of healthy urine and anasarca. Trousseau imagines that a flow of urine may take place backwards by the ureters into the kidneys, distending these organs and impeding their functions. It has suggested itself to me that part of the urine may be absorbed by the distended bladder; but, anyhow, the fact remains that the anasarca is unattended by any disease of the kidney.

The very fact that the results of experiment on healthy animals bring into such bold relief the results of disease in the human subject suggests the greatest caution in dealing with them as standards of reference in pathological questions. Such ingenious theories as those referred to, which have been constructed to reconcile the dissimilar phenomena, are thus *a fortiori* liable to be impeached as tending only to obscure the light which these experiments convey. And such truly I believe to be in great measure the case. When critically examined, the chief value of these experiments seems to consist in their leading to the reflection that disease does not shoot out its phenomena in an hour or two, but that it works long and often silently, is recondite in its nature, complex in its affinities, and usually fertile in its resources; that is to say, they indicate that in the elucidation of the phenomena of disease it is necessary to look deeper and more antecedent. And with respect to renal dropsy, I think there can be little doubt that its chief vital predisponent is that condition of the blood to which the term "anæmia" is conveniently applied. Clinical experience confirms this. "How is it," says Sutton, "that œdema is so prevalent in some cases and not in others? Frequently the renal symptoms—albuminuria, hæmaturia, giddiness, and shortness of breath—have come on, but with no appreciable dropsy. The dropsy is augmented with the increasing loss of red corpuscles, the coloured respiratory organs;[10] and it may be plausibly suggested that to the anæmia of Bright's disease as to chlorosis certain retained products of the organism, or their toxic derivatives, stand in a causal relationship. But, however originated, one of the most palpable facts in connexion with anæmia is failure of the blood adequately to carry on the circulation. Then, when to anæmia an hydræmic plethora is added, the conditions for the production of renal dropsy are fulfilled, whilst its distribution is regulated by physical laws. Consider the condition of matters. The blood, as already stated, is suffering intrinsically in progressive deterioration of its vital energy, particularly from progressive diminution of its corpuscles, which, by their mutual actions in the normal state, materially assist in the propulsion of the blood stream; it is, moreover, as Hamilton very appropriately insists on, signally impeded in its functions by alteration of its specific gravity. The plasma has become specifically lighter than the red corpuscles, which consequently cease to float with ease in the centre of the stream. Hereby the corpuscles, instead of assisting, only serve to retard the blood current, leading to increase of tension and the pressing out of a greater quantity of fluid than usual. But further than this, the specific gravity of the blood as a whole, from the advancing attenuation of its proteid constituents, is altered relatively to that of the plasma in the surrounding lymph-canalicular system, which will constitute another condition favourable to the transudation of the fluid within the bloodvessels; and such transudation will be rendered still greater by the loss of tonicity which the vessel wall shares in common with the rest of the tissues in this cachexia.

Now, in this hydræmic plethora, with its attendant difficulties of circulation, it is in accordance with dynamical principles that in those parts most remote from the heart—in the periphery of the body, namely—will the impediment be greatest; and, in accordance with the law of gravitation, the most dependent and the most lax of these parts will be specially involved. There the *vis a fronte* is greatest and the circulation is slowest; the venules become over-distended, and are unable to absorb and transmit the lymph which pours forth excessively from the capillaries. Should this state of matters continue, the circulation will fail nearer and nearer to the heart, until the fluid accumulates internally, in the serous cavities, lungs, and other organs, when death is imminent.

On the other hand, with regard to the phenomena which appeared in the subject of Cohnheim's experiment, their

explanation may not be so far to seek when it is considered that the blood and internal organs were vigorous and healthy to begin with. A continuous effort would naturally be made by the healthy organism to rid itself of the superabundant fluid by means of the natural channels. This would lead to venous engorgement in and around those organs whose functions were exalted. Such would notably take place in the abdomen where excretion has its seat, and hence the resultant ascites. But in disease these conditions are reversed, and the organism perforce seeks relief through other channels, for the excretory organs are appealed to in vain towards the riddance of a foreign element whose invasion they have been powerless to resist, and under whose yoke they are paralysed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE INHALATORY TREATMENT OF PHTHISIS BY MEANS OF SUPERHEATED AIR.

By ALEX. BOWIE, M.D., M.S.

IN order that the bacilli of tubercle may abundantly flourish, a temperature of 99° is a necessity. If the temperature be lowered to 84° or raised to 107·6° they are rapidly killed, their vitality diminishing as we recede in either direction from their normal point. Such a trivial rise as 3° above the normal temperature is sufficient to markedly retard their developmental energy. With these facts in mind, it is somewhat strange that, until recently, no one should have suggested a method by which diseases of the human being associated with or dependent upon the bacillus of tubercle might be treated by exposing the diseased surface to a temperature necessary for their destruction. The inhalatory treatment of phthisis is as old as Hippocrates, and apparently every conceivable method has been freely used, with the exception of superheated air. We have had fumigations with aromatic and stimulating substances, ranging from sea air to sulphurous waters, from pine cones to elaborated combinations of balsamic herbs. With the birth of chemistry the physical properties of the air received attention, and Henshaw crystallised the thought of the time by erecting, in 1664, his *Domicilium*, where acute chest diseases were treated by condensed, and chronic by rarefied, air. The inhalation of oxygen was followed by treatment with diluted air; and, finally, phthisical patients were recommended to spend a considerable portion of their lives in diving-bells, to obtain the advantage of compressed air. The introduction of sprays of medicated and natural thermal waters marked another advance, but each system fell more or less into disuse from insufficiently satisfactory results. My experience with the inhalation of superheated air has, so far, yielded results of a very favourable nature. The apparatus used was Weigert's, in which the temperature expired by the patient after a few trials may reach from 120° to 140°. The inspired air, according to the thermometer in the tube, may be as hot as 570°, but I do not think the actual inspired air is ever hotter than from 280° to 300°.

In February, 1889, I was consulted by a married man aged twenty-seven, who had been ill since 1885. He had suffered from recurrent attacks of hæmoptysis, and had expectorated as much as thirty ounces of blood in three days. He had cough and profuse muco-purulent expectoration, containing abundance of tubercle bacilli. There were loss of appetite, nausea, and vomiting in the morning, marked wasting of the body, and shortness of breath, with inability to lie down in bed. Both apices gave the physical evidence of phthisis. The first effects of the inhalations were a slight rise in temperature, generally about half a degree, increased rapidity of the pulse rate, and diminished frequency in breathing. These lasted from one to three hours after the inhalation. The cough and expectoration were increased, but showed signs of abatement after four weeks' treatment. His morning nausea and vomiting from the first disappeared, the appetite improved, his rest was less disturbed, and his sleep was more refreshing. His sputum, as it diminished in quantity, contained relatively less of the bacilli. At the present time there is no regular cough, and expectoration is absent. He complains of no shortness of breath; there is an increase of 4lb. in body weight, and the chest girth is believed to be larger. His appetite and digestion are good, he can lie down just as before his illness, and he performs the ordinary work of a shopman without any particular discomfort or consequent exhaustion. There are still present slight consolidation of his left apex, with slightly prolonged expiration, but these have diminished in a continuous line. During the treatment no medicine was prescribed. Cod-liver oil had previously been abandoned on account of gastric intolerance, but this was resumed three months ago, and has always been retained.

Since the improvement in the above case became marked, I have not hesitated to advise the treatment in several others, in each of which improvement in the disease and comfort of the patient have occurred. But the one case is, I believe, a sufficient reason for calling attention to a new and most hopeful means of treating an intractable disease.

Harley-street, W.

COLOTOMY SUCCESSFULLY PERFORMED FOUR DAYS AFTER CHILDBIRTH AND EIGHTEEN OF TOTAL OBSTRUCTION.

By H. GEARY DYER, L.R.C.P. EDIN., M.R.C.S.

THE following case, which I will report as briefly as possible, is, I think, of sufficient interest for publication.

On April 2nd I was sent for to see Mrs. S——, who was in daily expectation of being confined with her first child. She was then complaining of constant vomiting and constipation, for which I prescribed liq. bismuthi co. and hydrocyanic acid, telling her it was in all probability due to her condition, and that her symptoms would be relieved as soon as she was delivered of her child. I also gave her three grains of calomel for the constipation; but she experienced no relief to either symptom. At 3 A.M. on April 5th I was again called to her, as she was in labour. Nothing unusual occurred in the parturition, except that it was (as might have been anticipated in a primipara of thirty-five) a little lingering; no instrumental aid, however, was required, and the child was born in the ordinary manner at 9.30 A.M. No fæces escaped with the child, though there had been twelve days' total obstruction, and, on examining the rectum, I found it, to my surprise, perfectly empty. I could find no hernia in any of the usual positions for such swelling. On visiting her that night, I found the sickness still proceeding, but not stercoraceous; bowels still confined; temperature 101°; pulse 120; commencing swelling of the abdomen, which was tympanitic. The next morning (April 6th) I administered a warm soap-and-water enema, which, however, brought nothing away. I then introduced a long tube, and gave another enema with turpentine, the result being the same. I saw her again that night, and found the vomiting stercoraceous, the abdominal swelling greatly increased, the temperature 103°, the pulse 130, and the countenance most anxious. The next day (the 7th) Mr. Wyke-Smith, of Wimborne, kindly saw the case with me, and, finding my patient becoming rapidly worse, we administered chloroform and made a thorough rectal examination with hand and forearm introduced. The rectum was perfectly empty. An attempt made to pass the tube into the sigmoid flexure failed. A growth from the sacrum was distinctly felt pressing on the bowel, but there was no evidence of abdominal or uterine tumour. We both agreed that nothing could save the patient's life but operation, and made arrangements for performing this the next day. On visiting her then (April 8th) we found her anxiously looking forward to our arrival, but, although her "pluck" and sound common sense kept her up, her condition was most critical. The abdomen was so enormously distended that the intestine could be clearly mapped out on it; constant stercoraceous vomiting was still going on, and the pulse was so rapid that we could hardly count it. Dr. Batterbury, who had kindly accompanied his partner, Mr. Wyke-Smith, fully coincided with us as to the urgent need of an operation, and entirely agreed with our diagnosis as to a growth from the sacrum, causing obstruction by pressure on the rectum. My assistant, Mr. Hiley, was also present, and rendered me most valuable aid. I need not describe the operation I performed, which was that of left lumbar colo-

Digitized by Google

tomy. Suffice it to say that I had no difficulty in reaching the bowel, and, after stitching it to the skin in the usual manner and opening it, I was rewarded by witnessing the most enormous escape of semi-fluid fæces that I should imagine can ever have occurred, filling as it did upwards of three chamber vessels. From a temperature of 105° that night and a pulse of 145, both fell to normal within a week. The wound united splendidly. The patient was up in ten days, out of doors in a fortnight, and at the present time frequently walks four and five miles a day. She removes the plug night and morning, and keeps the motions perfectly inodorous with charcoal. There is a strong family tendency to cancer, but, as far as I can make out, there is at present no appreciable increase in the growth.

Ringwood.

ACUTE EPIGASTRIC PAIN IN PREGNANCY ASSOCIATED WITH ALBUMINURIA.

BY H. F. BAILEY, M.R.C.S., L.S.A.

THE following case presents so many points of interest that I venture to relate it in detail, trusting it may act as a warning to any brother practitioner who may meet with a similar condition.

The patient, a primipara, aged twenty-seven, was expecting her confinement on or about Feb. 24th. Her friends had noticed that she was unusually "fat" about the face and hands, and she was aware that her feet and ankles were swollen. Her chief complaint was of pain in the epigastrium, and was attributed to indigestion. I saw her on Jan. 23rd, and found œdema of the feet and legs up to the knees, but not well marked; the hands were certainly swollen, and there was puffiness about the eyes and face. She complained bitterly of the great pain at the epigastrium, passing through to the back; this characteristic was very marked later on in the progress of the case. On inquiry, I ascertained that she had partaken of oysters and spiced beef for luncheon, and hence rather acquiesced in the dyspepsia theory; but, on examining the urine, I found a trace of albumen. The pain was not always present; indeed, there would be none for some hours, and she would take a walk; but it invariably returned, and became more intense as time went on, reaching an acme and then declining. There was no desire for food, and her condition was one of absolute misery. The pain was so severe that often she writhed and sobbed with it. She assured me afterwards that the labour pains were nothing compared with those of the epigastrium; she always described them as cutting in character and passing through to the spine. At first I gave the ordinary remedies for dyspepsia, and regulated the diet; but these things entirely failed to relieve her, and all the symptoms became worse. In face of the albumen I did not much like giving opium; but to relieve her I sacrificed my scruples and administered good doses, which utterly failed. By Feb. 8th the sickness had become a marked feature of her case, and the pain was much increased in severity. Her mental condition was one of great depression. I found that the albumen had reached one-eighth. It was now evident I had an unusual and dangerous case to encounter, which might necessitate the induction of labour if eclamptic symptoms supervened. In casting about for guidance, I met with a paper by Dr. John Phillips[1] on this subject, where he draws attention to this rare and serious complication. Mr. Raven more recently has quoted from the same paper, and added a case of his own.[2] While deliberating on my plan of action, to my great relief labour came on prematurely on Feb. 10th. All went well, the os dilating, and the head descending rapidly. Suddenly the patient was seized with general rigidity, the hands taking the attitude of extreme extension, and the fingers being bent backwards. I gave a little chloroform, and delivered rapidly with the forceps. The child was starved and decrepit-looking, but thrived ultimately. The mother did well, all albumen disappearing on the second day. She had absolute immunity from pain after the labour terminated. The only drug of any use was cocaine, which, however, I only discovered to be of service just before labour began.

The above case seems a typical one in its course and symptoms, and for this reason I have felt it right to add it to those already placed on record.

WEST LONDON HOSPITAL.

FIVE RECENT CASES ILLUSTRATIVE OF CEREBRAL SURGERY; REMARKS.

(Under the care of Mr. C. B. KEETLEY and Drs. DONALD HOOD, J. B. BALL, and COLMAN.)

THIS group of cases, the first of which we give this week, are worth recording, owing to the difficulty which still attends accurate diagnosis and correct judgment in the treatment of cerebral cases. Case 1 illustrates the value of operating mainly with the object of cleansing and asepticising the wound. Without the use of the trephine (or of some substitute such as the chisel and mallet) the bullet track could not possibly have been thoroughly cleansed of bone-splinters, "grime," and the piece of loose bullet found and removed. This case is also one of those extremely rare ones in which recovery, probably permanent (as nearly a year and a half has now passed safely by), with a bullet, or at all events the major part of it, remaining in the cranial cavity. In Case 2 the diagnosis of cerebral abscess may not be absolutely proved, as no pus appeared until three or four days after the trephining. But there are several considerations which point to this pus having come from an abscess opening itself through the trephine hole: (1) Under the microscope the pus cells were found extremely granular, and accompanied by a great deal of granular débris; (2) it came suddenly in comparatively large quantity, and a small stream overflowed from beneath the dressing for a short distance down the neck; (3) the pain in the head, the tenderness of the right orbit, the optic neuritis, and, in fact, the very symptoms which had preceded the operation and led to it, suddenly abated, and the patient was at once convalescent; (4) the suppuration did not continue; (5) the whole of the disc of bone, which had been replanted in small pieces, lived—not one necrosed; (6) the symptoms had so strongly pointed to cerebral, or at all events intra-cranial, abscess. There is a case reported by Sir William Stokes,[1] in which he only missed, "by the twentieth part of an inch," a traumatic subdural abscess "containing fully two and a half or three ounces of healthy, cream-coloured pus"; in fact, just the kind of pus which escaped from my case. Had Sir William Stokes' patient not died the day after operation, it is surely likely that in a few days the abscess would have opened itself, as in this case. It is not unlikely that in Elizabeth W——'s case the abscess was subdural and traumatic, and that each exploratory puncture of the trocar used passed internal to it. Two of the five cases illustrate a method of preserving a button of bone destined for replantation. A small longitudinal incision is made in the skin of the outer side of the thigh (other parts would do very well). With strict antiseptic precautions, including the previous preparation of the part of the thigh selected, the button is pushed through this incision into a subcutaneous pocket, and there retained with an antiseptic sponge or bandage until wanted. It is finally chipped into small pieces with bone forceps over the trephine hole and beneath a sponge. Mr. Keetley wishes to express his great obligations to Dr. Colman for assistance in the management of Case 2. The primary diagnosis was due to that gentleman. Cases 2, 3, and 4 were watched and reported by Dr. Sidney Bontor, Case 5 by Dr. Arkwright, and Case 1 by Dr. S. S. Sprigge. Dr. Percy Lush, as house physician, reported the first part of Case 3.

CASE 1. *Bullet wound of brain: trephining, partial extraction of bullet, drainage, recovery.*—E. H——, aged fourteen, was admitted into the accident ward on March 22nd, 1888. He accidentally shot himself in the left temple with an old

[1] Annals of Surgery, vol. viii., p. 243.

Digitized by Google

revolver about nine o'clock that evening. The wound ran diagonally from about the centre of the temple backwards, outwards, and a little upwards—i.e., towards the upper part of the left temporal fossa. With the probe metal could be distinctly felt at no great distance from the point of entry. There were no cerebral symptoms, except vomiting.

March 23rd.—The operation was performed at 1.30 A.M. One-fifth of a grain of morphia was administered subcutaneously and chloroform commenced ten minutes afterwards. A horseshoe-shaped flap was turned downwards, exposing the bullet wound in the skull and the bone to the left of it. The track of the bullet was very oblique and towards the left. A small piece of lead was found immediately beneath the periosteum at the opening in the bone. A circle of bone, the size of a shilling, was removed from the left side of the bullet wound, and the first inch of the bullet track thus exposed. It was grimy and contained splinters of bone. It was carefully cleansed. A silver probe found its own way along the track till its point impinged on the inner surface of the cranium in the temporal region. There an irregularity could be felt. A fine pair of bullet forceps was passed down to this, which proved immovable, and was therefore left alone. A fine drainage-tube was passed in (for about four inches and a half), having a double loop of catgut in it. The soft parts of the wound were scraped and cleansed of grime. Iodoform crystals and gauze dressings were applied. The patient vomited frequently during the dressing and several times during the night.

24th.—Sick again this morning. Quite sensible. Bandage relaxed. Morning temperature 99°, evening 101·2°.

25th.—A little headache. No vomiting since noon yesterday. Quiet night. Morning temperature 100°, evening 100·6°.

26th.—Bowels freely opened after enema. No more vomiting. Continues sensible. Temperature normal. Wound dressed in the evening. Not much oozing into dressing. Wound looks well, but there is a little puffiness over the forehead and eyelids. Catgut loop withdrawn from inside the drainage-tube (which was not blocked). Tube drawn out a little and shortened three-quarters of an inch. Same dressing repeated with a small sponge over it. Ice-bag continued. No pain. Morning temperature normal, evening 99·8°.

27th.—No pain. Taking milk and beef-tea freely. Morning temperature 99·8°, evening 99·8°.

April 4th.—Distinct pulsation can be felt over the trephine wound; dressed for the third time and drainage-tube removed. A sponge was strapped over the dressing, the strapping encircling the whole head. Low diet still continued.

16th.—Dressing felt a little uncomfortable. Temperature rose in the evening to 100° for the first time since the second day after operation.

17th.—A drop of atropine having been placed in the left eye preparatory to ophthalmoscopic examination, the patient became angry and much disturbed, probably through misunderstanding and fright, and would not permit anything further to be done.

On the 23rd meat diet was given for the first time, and on the 28th he was discharged.

Remarks by Mr. KEETLEY.—He has been seen many times since both by myself and Dr. Gardner of Mill-hill Park, who attends his family. There of course remains a cutaneous scar and a deficiency in the bone, but otherwise he is well. The operation, including the trephining itself, was done as much with a view to cleansing and asepticising the track as with the hope of extracting the bullet. The result was that, instead of there being left a narrow, dirty, perhaps inflamed and sloughing canal, containing burnt powder and bone splinters, and ending at one extremity in the brain, there was a perfectly clean and aseptic tube of flesh and blood conducting a small soft drainage-tube down the bullet track in the brain, perhaps to its termination. A second point to be noticed is that the patient was kept over a month in bed on milk and beef-tea diet. The importance of keeping such a case quiet and unexcited for a long time is obvious. No one hesitates to keep a case of typhoid fever on prolonged milk diet. This boy was suffering from a condition much more dangerous and incomparably less exhausting than typhoid fever. Next to asepsis the prime indication was to secure quiet, physically and physiologically, and, especially in a healthy boy of fourteen, an unstimulating diet is not only antiphlogistic, but also helps to keep the patient tame and obedient. Where is the part of the bullet (almost the whole of it), and is it likely to cause future mischief? I would first ask—Is it possible for a narrow revolver bullet to pass through the motor centres in the cerebral cortex, or through the subcortical fibres radiating to them, without causing either paralysis or spasms? I should like to hear the opinions of Professors Horsley and Macewen on this point. I myself think it may be possible, but that it is not likely. I therefore think that the bullet in Edward H——'s case lies anterior to the motor area, and that it is lodged near the base of the left middle frontal convolution, I hope partly embedded in the dura mater and frontal bone there, and encysted. If the bullet had not been fixed, would it not before now have gravitated downwards during the day and backwards during the night? Such gravitation should have produced symptoms. Ten months have now passed over in safety. The bullet may by this time have slipped down to the roof of the orbit, and there become fixed and harmless. But if it continues to move backwards and downwards, sooner or later symptoms should appear, especially aphasia, and (much less likely) facial paralysis of cortical origin, or else some affection of the cerebral nerves at the base of the brain. The patient has the advantage of being under the continued observation of Dr. W. T. Gardner; he can be easily and promptly returned to the hospital at any time should any symptoms occur to localise the bullet, and I hope he is in a fair way to remain one of the few cases in which a bullet has lodged in the brain and practically complete recovery taken place without extraction of the missile. I should add that the left temporal fossa and its neighbourhood have been repeatedly examined, with negative results.

MARGATE COTTAGE HOSPITAL.

AMPUTATION OF FOOT, WITH RAPID UNION, IN SPITE OF SYPHILIS, GOUT, AND DELIRIUM TREMENS; REMARKS.

(Under the care of Mr. BERTRAM THORNTON.)

THIS case presents an example of recovery from amputation of the leg when many constitutional conditions unfavourable to rapid healing were present. Mr. Thornton attributes the success chiefly to the antiseptic treatment employed.

The patient, a debilitated man, aged thirty-eight, was admitted early in February, suffering from disease of the right tarsus, which eventually turned out to be of a tertiary specific origin. Mr. Treves, who first had charge of the case, made incisions into the foot and got away some necrosed bone on Feb. 22nd. In spite of the operation, the foot remained swollen and inflamed, and the evening temperature varied between 100° and 101°. As the man was rapidly going to the bad, and the foot began steadily to get worse, it was decided to amputate in spite of the man's unfavourable condition, for already he had characteristic gouty inflammation of several joints. On March 3rd, in Mr. Treves' absence, Mr. Thornton amputated the foot three inches above the joint by Teale's method, using the ordinary antiseptic precautions; two small drainage-tubes were inserted at the angles of the wound, and iodoform oil and liberal absorbent wool dressings applied. The amputated foot was totally disorganised, and had the horribly offensive odour so often met with in syphilitic bone disease. The amputation wound healed steadily and well, and by the eighth day was firmly healed, with the exception of two small superficial places at the angles of the wound.

Remarks by Mr. THORNTON.—The interesting features are—firstly, the extreme debility of the patient; secondly, the syphilitic condition leading to the operation, which condition was proved by the history of the patient and the evidence of scars about the legs; thirdly, the gouty inflammation of various joints before the operation and for a fortnight afterwards; and, fourthly, the onset of alcoholic delirium, with visions of a big black dog &c., two days after the operation, lasting more or less for a week or ten days. To add to the patient's danger there had just been a very bad case of erysipelas in the adjoining ward, from which he was mercifully spared. It is rare that an amputation should heal so readily under such extreme and varied pathological difficulties. In this case there were two more interesting features which are worthy of note, the first being the formation of an abscess extending from the head of the fibula to within two inches of the operation wound, with which it had no connexion whatever. It appeared to me

Digitized by Google

that it might be due to the pressure of the Esmarch's india-rubber tourniquet, which was used with the ordinary amount of tightness at the operation over the old specific scars. Eighteen days after the amputation the patient was anæsthetised, and I opened the abscess above and below, and, as a second interesting feature, I pulled out a firm pyogenic membrane, which had the appearance and consistency of the fœtal membranes. A drainage-tube was passed through the cavity of the abscess, and membrane was discharged for about a week afterwards; and in another ten days the abscess cavity was obliterated and the two wounds quite healed. The case presented so many features of interest that I thought it worth recording. The surgeon has frequently to risk operation in syphilitic and alcoholic cases, but he is rarely called upon to operate in acute gout, and more rarely still in the presence of all three, to say nothing of the dread shadow of erysipelas in the background. The fact that this man successfully ran the gauntlet of all these foes speaks well for the blessings of antiseptic surgery, or at any rate for the vitality of the human race at the close of the nineteenth century.

Notices of Books.

A Treatise on Chemistry. By Sir H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S. Vol. III.: The Chemistry of the Hydrocarbons and their Derivatives, or Organic Chemistry. Part V. London and New York: Macmillan and Co. 1889.—This is the eighth volume of the great English work so well known to and so highly valued by English chemists. It is hard to guess when it will be completed, as there are still many important groups of compounds to be described; and we trust that a final volume, or at any rate an appendix, will give more detailed information in regard to physical and particularly to thermal chemistry, than has yet been afforded. The great merits of the treatise are its convenient classification and lucid style, the numerous references to original memoirs with which it is illustrated, and the admirable historical sketches, sometimes extending backwards to Ancient Egypt, Assyria, India, Arabia, Greece, and Italy, with which every important substance is introduced. This last feature gives constant interest as well as additional value to the book, and a good example is afforded in the present volume, where the history of discovery in regard to the terpenes and camphors is traced from Dioscorides and Pliny to Tilden and Shenstone in our own day. Each part—that is, each volume—of the organic portion of the book is complete in itself, and forms a monograph on some important series of compounds. The last two volumes (Parts 3 and 4) have been devoted respectively to the derivatives of benzene and of toluene and xylene. The present volume (Part 5) begins with ethyl-benzene and the styrolene group, in which amygdalin and isatin are included. It would perhaps have been more convenient if this group could have found a place in the previous volume. Then follows the cumene group. Nine hydrocarbons having the formula C_9H_{12} are now known, and they, as well as their leading derivatives, are sufficiently described. Cinnamic acid is at present the most interesting member of the group. About half way through the book we are introduced to the aromatic hydrocarbons containing more than nine atoms of carbon—the cymenes, of course, coming first. They are chiefly interesting because they almost certainly include the highly important terpenes and camphors, as well as caoutchouc and gutta-percha. The volume ends with an account of the last-named bodies and one or two allied substances.

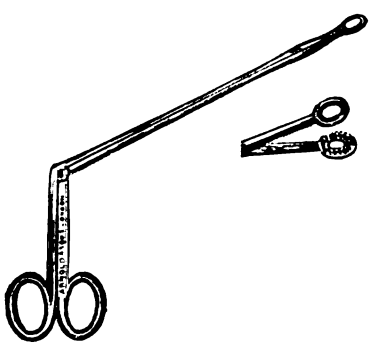
Lessons in Gynæcology. By WILLIAM GOODELL, A.M., M.D. Third Edition. Philadelphia. 1887.—The review of a third edition of this book concerns principally the question of its revision to the level of present knowledge. This cannot be said to have been accomplished, notably in the case of pathology; for we find the old and incorrect statements as to the effects of flexions on the uterine circulation, as to the pathology of uterine cancer, and as to many other important diseases. Since practice must be based on pathology, our criticism is not merely pedantic. Some of the earlier chapters, being apparently clinical demonstrations on minor ailments, are graphic and practical, and there is much that is good in the work. No book, however, can be a sound guide for the student and practitioner unless it is abreast of the times; and in this respect the present work shares the fate of many others, when the author becomes too busy to read.

The Neuroses of the Genito-urinary System in the Male, with Sterility and Impotence. By Dr. R. ULTZMANN, Professor of Genito-urinary Diseases in the University of Vienna. Translated by GARDNER W. ALLEN, M.D., Surgeon in the Genito-urinary Department, Boston Dispensary. Boston: Cupples and Hurd. 1889.—The title of the work fully describes its scope, and the name of the author is ample guarantee for its thoroughness and systematic completeness. The translation is very poor, and the reader never loses the consciousness of reading a German book. It is not divided into chapters, there are no page headings, no table of contents, no index, and what may be called the editing of the book is extremely faulty. This will quite prevent its ever being a popular book.

Spinoza, "the God-intoxicated Man": a Short Account of his Life and Philosophy. By WILLIAM JOB COLLINS, B.Sc., M.D., &c. Enfield: Meyers, Brookes, and Co. 1889.—This little pamphlet contains an interesting sketch of the life, character, and teachings of a philosopher whose history and writings are still comparatively little known in this country. The author is probably right in attributing much that is distinctive in the nature and utterances of Spinoza to the influence of early personal and hereditary associations. Born of a Jewish family domiciled in Spain under the Moors, but afterwards exiled and established among the free and energetic Hollanders, he had on his side many circumstances favourable to the development of a mind at once artistic and philosophical, not wanting in worldly shrewdness, but remarkably sincere and disinterested. His frugality was conspicuous, and his unselfish devotion to principle came out in a pleasing light in his refusal, not only of honours which involved a retraction of his opinions, but of emoluments, like the legacy of De Vries, which he felt to be superfluous. In the treatise before us his religious and philosophical views, derived from his "Ethics" and the "Tractatus Religio Politicus," are explained with considerable clearness. His idea of the nature of God as an essence pervading all things, if its very vagueness proclaims that nature to be unfathomable, at all events frees him from the imputation of atheism. Christ is to him a singularly perfect man, and something more. He is the Eternal and embodied Wisdom of God to whom the Divine Mind directly and habitually revealed itself. There is a good deal of truth in his observation respecting the separate but mutually compatible spheres of faith and philosophy. The same might be said of his assertion that prophecy is a sort of skilled and often truthful imagination, and that miracles form a group of peculiar natural or not contra-natural phenomena. He justifies free thought in religion and in politics, and reasonably enough when we consider that he was himself most cautious in his freethinking and most free from dogmatism. This moderation in thought and statement is a mark of the sense of order which rules the mind of every great thinker; and it is, in our opinion, not the least notable point brought out by Dr. Collins in this brief history of a remarkable man.

Sinonia Chimico-farmacotecnica di Salvatore Di-Giorgi, Chimico-farmacista in Mazzara del Vallo. Milano, a spese dell' autore, 1889.—This little dictionary of chemical and pharmaceutical synonyms, though it does not refer to terms

Digitized by Google



in other languages than Italian and Latin, will be of use to medical men and chemists who have occasion to look at or to make up prescriptions coming from several parts of the Continent, many of the terms in Italian being similar to those used in Spanish, and a good many Latin terms being inserted which are used in several continental countries, though almost unknown here, and therefore likely to puzzle an Englishman somewhat. For example: "Cianuro" in both Italian and Spanish is cyanide—a perfectly obvious fact after one is told it, but not quite so easy to evolve from one's inner consciousness without any hint to go upon. "Electuarium thericale magnum" is not a preparation of which most of us know anything, but by looking it out in Signor Di-Giorgi's work we at once become aware that it must be treated with caution, as one of its synonyms is "elettuario d'oppio composta," which would convey to the mind of any medical man or chemist, even though he might be entirely innocent of any knowledge of the Italian language, that he had an opiate to deal with. The work of course makes no attempt to give the strengths of the various preparation, nor does it say to what Pharmacopœias the different terms belong, so that the preparations grouped together as synonymous must only be taken as approximately so. This is, however, a defect which it would have been impossible to have avoided without very largely increasing the bulk of the little volume.

Mechanics and Experimental Science, Magnetism and Electricity. By ED. AVELING, D.Sc., Fellow of University College. London: Chapman and Hall.—Dr. Aveling's books, as we have already remarked, would seem to be designed to subserve the purpose of cramming, and even of cramming for the London University examinations. Hence they are very fragmentary, and although some of his expositions are highly successful, other parts of his work are of such unequal quality that, upon the whole, it attains only a modest standard of excellence.

New Inventions.

A NEW AURAL FORCEPS.

THE instruments which mark the growth of a specialty have a clumsiness directly as the development of such specialty. The instrumentation of aural surgery forms no exception to this rule. Many forceps designed for the removal of small polypi and granulations are so bulky as to obscure, on their introduction into the auditory meatus, the structure to be removed. Aural forceps have been constructed with the handles at various angles to the blades to obviate this difficulty, but the elements of delicate workmanship, strength, and appropriate shape are only met with in a comparatively small number of cases. These qualities, in my opinion, exist in an aural forceps which Messrs. Arnold and Sons of Smithfield have constructed for use. It is a modification of one which these makers supplied me with. The instrument consists of two blades placed at an angle of about 45° to the handles. The lower blade and handle consist of one piece, and are thus the fixed point of the instrument; the upper blade, together with the handle, consists of three portions. On separating the handles, the fine fenestrated end of the forceps is made to gape and grasp the object to be removed, and on approximating them the seizure is effected. The freely mobile portion of the blades is only about half an inch long; the entire blades to the angle, about four and a half inches. The accompanying woodcut reveals the above details; and after a considerable experience of such instruments, I have no hesitation in stating that this is the most convenient and efficient I have ever used.

ALEXANDER MORISON, M.D., F.R.C.P.E.

TREATMENT OF SCROFULOUS GLANDS.

To the Editors of THE LANCET.

SIRS,—I have read in THE LANCET of Aug. 24th an article on the Erasion of Scrofulous Glands, and in your issue of this week a letter from Mr. Thornton on the same subject. Surgeons interested in the treatment of scrofulous glands seem to be divided into three classes: (1) those who advise leaving the infected glands to the curative efforts of nature, or who advocate various medicinal remedies or local applications rather than operative measures for removal; (2) the advocates of erasion, amongst whom I may include the writer of the article; and (3) those surgeons who recommend excision. I have excised scrofulous glands for many years, and certainly, if I were compelled to limit myself to one of these three lines, I should take the last—viz., excision. But, fortunately or unfortunately, the matter does not lie in so narrow a compass; scrofulous glands present infinite variety, and the treatment which is best for one case may be the worst for another. It appears to me that each is right or wrong according to the individual character of the particular case, and that to lay down a line of treatment, whether expectant or operative, without seeing the patient is to take a leap in the dark and to formulate a general rule which has no general application. It is a nice point to determine the exact moment when a gland becomes scrofulous, and, this matter settled, the line of treatment depends so much on the patient and the state of his glands that no universal rule can be given. It is useless to say in a general and positive manner that scrofulous glands should be left to nature or treated with drugs, or that they should be scooped or cut out. Many glands cannot be scooped; others it is equally impossible from their attachments or position to excise; and fewer, if any, are amenable to drug treatment. Often it is better not to interfere for a time, but rather to wait till the general health has become established, till the disease has quieted down, and till such inflammatory products as can be absorbed have disappeared. In other instances, a softening gland may be causing so much irritation, and so rapidly infecting other glands, that it must be dealt with at once. Occasionally glands which have uniformly softened may be scooped, with the rosy results described by the writer of the article. In other cases the glands are such that they must either be excised or left alone. All that can be suggested generally is that it is not well to leave scrofulous glands for an indefinite time to increase and infect healthy glands; that scooping is often the best method for cases of small or moderate enlargements with general and uniform softening; and that excision, combined or not with some scooping, is the only method available for big enlargements, or for cases in which the glands have not softened, or for those in which caseation or softening has only taken place in limited portions of the glands. I am an advocate for excising scrofulous glands, but I should be very sorry to recommend excision as a universal practice, or, in fact, to lay down any general rule for the treatment of this troublesome affection. Each case must be judged on its merits and treated accordingly.

I am, Sirs, yours obediently,

Margate, Sept. 1st, 1889. WM. KNIGHT TREVES, F.R.C.S.

THE PROPOSED INFECTIOUS DISEASE HOSPITAL AT BLACKBURN.—Energetic opposition is being offered by prominent citizens of Blackburn against the erection on the site proposed by the Health Committee of a hospital for the reception of patients suffering from infectious disease. Last week a meeting was held in the Audley district, at which a resolution was carried condemning the committee's proposal.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 14, 1889.

THE recent localised outbreak of enteric fever at the West-end of London has produced an abundant crop of complaints as to the prevalence of nuisance from the metropolitan drains and sewers, and there can be but little doubt that the complaints are, in the main, fully justified. One of the evils under which Londoners suffer is a divided jurisdiction as regards sewers and drains. The main sewers belong to the County Council, whereas the state of the drains leading from the houses to the sewers, as also of the street gullies, comes within the jurisdiction of the several vestries, and a remedy applied by one authority to one set of conduits often leaves an evil connected with the other set altogether untouched. As to the sewers themselves, it is well known that some of the main underground culverts are in a very defective state—as, for example, in the somewhat low-lying districts of Westminster; and it is notorious that no system of ventilation can be adequate in the face of faultily constructed sewers. Then again, when sewer ventilators have been found to constitute a nuisance, they have simply been closed. This, however, as some correspondents point out, is no remedy; for, unless some alternative means of ventilation is provided, the risk of forcing foul air into houses, where it will do even more harm than in the streets, is greater than ever.

House drains should, of course, be so constructed as to prevent any such evil result, and this consideration brings us to a second evil from which London suffers in a very special way. Throughout the country generally excellent codes of bye-laws of modern date have, during the last ten or fifteen years, been adopted on a wide scale; and these provide, amongst other things, for such arrangement of house drains, and for such means of connexion between house drains and the public sewers, as practically to prevent risk of foul air passing from the sewers into dwellings. But in London no such regulations exist, and whilst a few of the more intelligent are having their house drains reconstructed on the modern principles, which include disconnexion and through-ventilation, hundreds of houses are annually being newly constructed which involve nearly all the evils attaching to the old ones of a past generation. And not only is there no power to prevent this, but the officials employed on behalf of the authorities to look after new buildings are often incompetent even to advise builders and others how they may, without noteworthy increase of cost, avoid for their future tenants many of the evils now so loudly complained of.

Mr. F. WOOTTON ISAACSON has given notice that at an early moment next session he will bring in a Bill making it illegal for house agents or for anyone else to let or sell a house unless a certificate is produced, furnished by a Government inspector, notifying that the premises are in a perfectly sanitary condition and fit for occupation. Without entering into the question as to whether the House of Commons will consent to pass such a Bill into law, we may note that, if such a law applied to the country as a whole, which it certainly should do if adopted at all, a very large number of experts will be required, and it is only necessary to read the recent correspondence as to the complaints referred to, to learn that amongst architects and surveyors who now advise local authorities the number whose claim as to expert knowledge on the subject would be accepted is a very small one. And it may be further noted that, as regards new dwellings, this is the wrong way to go to work. Legislation is required as to the construction of new buildings; and nowhere is this more needed, in so far as healthiness of houses is concerned, than in the metropolis, where the regulations are in many important respects antiquated and quite insufficient to meet the demands of modern requirements. Mr. ISAACSON'S Bill will, we fear, only touch the fringe of a subject that needs to be dealt with in a comprehensive manner.

THE clinical significance of the presence of albumen in the urine is a subject which has recently reappeared in our pages, and its great importance, as well as its great difficulty, more than justify all the attention that has been bestowed upon it. There can be no doubt that, without prejudging questions which are still *sub judice*, some real change has taken place in professional opinion upon the subject. A decade or two ago, if the question had been put, "What is the significance of the persistent presence of albumen in the urine, and what is the prognosis in such cases?" but one answer would have been forthcoming—viz., that such cases were instances of organic disease of the kidneys, and that the most probable outlook was death within two years. This answer can no longer be given with safety. That it would be true of a very large number, possibly the vast majority, of such cases is very probable; but we have come to recognise that there are exceptions, and that it is our business to determine how these may be recognised with reasonable certainty. In fact, albuminuria, which was long regarded as absolutely diagnostic of grave disease, is now recognised as only a symptom—usually a most serious symptom, but nevertheless one that does not exclude the necessity of further inquiry, or relieve us from the obligation of doing our utmost to interpret it correctly. As has been well said, we may compare albuminuria with hæmoptysis. If a patient spits blood frequently, there is a very high probability that he has tubercle in his lungs; but it is a question of probability, not of certainty, and in exceptional cases even frequent blood-spitting is not followed by any evidence of tubercular mischief. So with albuminuria. Its presence most strongly suggests the existence of organic renal disease; but we have to abandon the attitude of dogmatism with regard to this symptom, and admit that it may coexist with perfect health.

Dr. PAVY has well emphasised the cardinal distinction, without regard to which all discussion of this question must be dangerously misleading. The distinction is this—that it is only in cases in which albuminuria has existed for some considerable time, *without the development of any other symptom whatsoever*, that we are justified in seriously entertaining the idea that its presence may be free from grave danger. If any other symptom usually associated with Bright's disease—such as vertigo, dyspnœa, anæmia,

Digitized by Google

persistent dyspepsia, high tension in the arteries, serous inflammations, or retinal changes—coexists with albuminuria, the case at once passes out of the category of mere functional disorder, and becomes of the gravest character. It is obvious, therefore, that in dealing with a case of albuminuria our first duty is to exhaust all our methods of diagnosis in order to determine whether any of the symptoms enumerated above are present, even very slightly, and not to rest satisfied until the fact of their absence is assuredly determined. Nothing can be more vexatious or injurious to the practitioner than to diagnose a case of albuminuria as one of the rare exceptions, when the development in a few days of some symptom shows to demonstration that, on the contrary, it comes under the very common rule.

It seems to us that rather too much has been made of those cases of albuminuria appearing under forced and unnatural conditions in health. Extreme physical fatigue, intense mental excitement, and some other causes have been shown to be capable of producing temporary albuminuria, and this fact has been much relied upon by those who advocate what may be regarded as the newer views upon the subject. It is doubtful, however, if we are justified in drawing any definite conclusions from symptoms appearing under conditions entirely without analogy to those usually prevailing. A person ascends an Alpine peak, and has an attack of hæmoptysis. This only proves, what no one ever doubted, that a sudden and extreme alteration in the conditions of blood-pressure may cause hæmorrhage, but it helps us little, if at all, to determine when hæmoptysis occurring under normal conditions is due to organic disease and when it is independent of such. A parallel reasoning may possibly apply to those cases of albuminuria occurring under peculiar and highly abnormal conditions. The fact is interesting and worthy of careful note, but we must be very chary of reasoning confidently from it.

The abstruseness of the subject is shown by the fact that even the presence of casts, so long relied upon as absolutely diagnostic of organic disease, does not justify any final conclusion. Their presence is very noteworthy. If they are numerous and constant, the probability of Bright's disease becomes almost a certainty. Their character is capable of affording important guidance. But the remarks already made upon albumen apply almost without alteration to casts—viz., that while their presence is highly significant, we must note that presence as only a most important element in our diagnosis, and not as conclusively determining the whole question.

Cyclic albuminuria, or cases in which albumen appears in considerable quantities at intervals, the urine being free from it in the interim, has attracted much attention since it was first described by Dr. PAVY. It would appear, as might almost have been conjectured, that such cases are somewhat favourable relatively, and perhaps approach nearest to meriting the designation of "functional." This term reminds us how much this question has been one of nomenclature. Whether "physiological" albuminuria is a justifiable expression has been hotly debated, and it has been argued with much force that we might as well talk of physiological epistaxis or physiological hæmoptysis because bleeding from the throat and lungs may occur under abnormal conditions in health. The correctness of the analogy may be contested, but probably Dr. GAIRDNER is right in preferring the expression "functional" albuminuria. This, we presume, involves no hypothesis beyond the assumption that albuminuria occurs apart from discernible organic disease, and that this occurrence must be due to some aberration of function. These assumptions are hardly any longer contested.

We may sum up the present state of medical opinion on this most difficult question by saying that the persistent presence of albumen in the urine is a most grave symptom, and in the great majority of cases is indicative of organic renal disease; that, nevertheless, this rule has some rare exceptions; that we are only very slowly seeing our way to the detection of these exceptions, but that we may best hope to avoid error by invariably taking a comprehensive view of each case, by allowing each symptom its due weight and avoiding the drawing of conclusions from one symptom only, by postponing any important decision until time may have helped to the clearing up of difficulites, and by deriving all the help we can from considerations of history and etiology.

FOR some reason or reasons the Scotch people seem to take their lunacy quietly, and with much less show of obstreperous and litigious resistance than do the English people. It would be highly interesting, if it were possible, to work out how far this difference is referable, on the one hand, to characteristics and peculiarities of race, and to the influence of domestic life, habits, and education; and how far it is referable, on the other hand, to the action of the lunacy laws in each country, and to the system of management and the nature and quality of the supervision. Certain it is that there is a "happy-family" sort of air about lunacy affairs in Scotland which appears to be but vainly sighed for in England.

The thirty-first Annual Report of the Commissioners in Lunacy for Scotland is a record, not only of the state of the insane in the various establishments, but also of the relations which lunacy bears to the social and domestic life of the country during the year 1888. The Commissioners state that on Jan. 1st last they had official cognisance of 11,954 insane persons in Scotland, and that the proportion of all lunatics to the population reached in this year its highest record of 289 per 100,000. This is a proportion of 1 lunatic in every 346 of the population—a proportion which is only slightly less than that for England, which is 1 in 344 for the same year. Of the 11,954 Scotch lunatics, 1893 were maintained from private resources, 10,004 by parochial rates, and 57 at the expense of the State. There was a total increase of 309 in the number of registered lunatics in asylums and other establishments, and an increase of 26 in the number of registered lunatics accommodated in private dwellings. The number of voluntary patients admitted into asylums in 1888 was 55, and the Commissioners continue to be of opinion that it is a useful provision of the law which permits persons who desire to place themselves under care in an asylum to do so in a way which is not attended with troublesome or disagreeable forms, but which nevertheless affords sufficient guarantee against abuse. The recoveries (discharged) per cent. of admissions in the different classes of establishments were as follows:—In Royal and district asylums, 38; in private asylums, 25; in

Digitized by Google

parochial asylums, 45; in lunatic wards of poorhouses, 7. But it is to be observed that in this statement private and pauper patients are not distinguished, nor is the effect of transfers eliminated so as to afford a just appreciation of the comparative proportion of recoveries in the different classes of establishments. The death-rate per cent. of the number resident was for private patients 6·4 and for pauper patients 8·1. The number of escapes in 1888 was 209, being rather less than the average proportion for the last ten years. The reported accidents numbered 95. Of these, 9 (including 4 suicides) ended fatally. In 40 cases the accidents involved fracture of bones or dislocation of joints.

While referring the progress made to beneficial changes introduced during the year in some of the institutions, the Commissioners speak in highly favourable terms of the management and administration of the various asylums under their supervision.

With regard to private patients in private dwellings, the Commissioners state that it is not required by the Statutes that all of them should be under their supervision. The circumstances which bring under their supervision an insane person who is not a pauper and who is not placed in an establishment are the following: 1. If he is kept in a private house for profit, and suffers from mental disorder of a confirmed character. 2. If, whether kept for profit or not, he has been insane for more than a year, and is subjected to compulsory confinement to the house, to restraint or coercion, or to harsh and cruel treatment. 3. If he possesses property which has been placed under curatory by a court of law. The Commissioners state that they do not regard it as desirable that any class of persons should be brought under their official supervision unless such supervision appears to be necessary to guard against abuse.

The Commissioners embody in their report some valuable information supplied by their deputies on the important subject of the boarding-out of pauper patients in private houses, and show the advantages derivable therefrom.

The report deals at length with the following instructive subjects: the influence of season on asylum statistics, the length of time during which patients remain in establishments, and the ages of the insane; and it concludes with a brief summary of the statistics of lunacy in Scotland from 1858 to 1889. From this summary it appears that the number of lunatics officially known to the Board and on their registers has increased in the thirty years from 5823 to 11,954—i.e., the number has more than doubled itself. The increase of the population during the same period has been only 34 per cent., and the Commissioners go on to say that they have frequently pointed out that the difference in these rates of increase does not necessarily indicate an increasing amount of mental disease, and that it is probably due in a large measure to what is only an increasing readiness to place persons more or less disordered in mind as lunatics in establishments. The use of the term "increasing readiness" in this relation, and as applied to what is really a decreasing unwillingness, is not free from a risk of being misconstrued into meaning more than (we believe) it is intended to mean. But apart from this, there is a vagueness in the expression of opinion here stated which leads us to believe that our information, as given by the Commissioners in Lunacy for Scotland, is not yet completed on this all-important topic. Surely, after so many years of methodical consolidation of our lunacy systems, we have a right to expect that before long we may be able to have a more definite answer as to whether the proportional increase of registered lunatics to population is merely the outcome of our present methods of dealing with the insane, or whether it is to be taken as implying that insanity is really on the increase in our midst. The adjustment of the evidence in the matter is no easy one; but if our lunacy legislation and developments have in any sense attained their object, and if our progress in the working of lunacy departments has been at all commensurate with the trouble taken, the old stock explanations of twenty-five years ago, as to accumulations of chronics and the like, ought sooner or later to wear themselves out.

HABITUAL DRUNKENNESS may be decreasing, but it is still a painfully common disease, as every practitioner of any experience could tell. True, he does not tell. It would astonish the public if medical men were to reveal all they know of this class of cases. But there is one document which year by year brings this subject into public notice, and imposes on ourselves the duty of some criticism. We refer to the Annual Report of the Inspector of Retreats acting under the Habitual Drunkards Act, or, to use the new title, given in the amended and permanent Act of 1888, the Inebriates Act. The present report is the ninth, and may perhaps be considered, on the whole, satisfactory; though, as we read it, and in the light of the great frequency of habitual drunkenness, it admits of being very differently regarded. There were only seven establishments or retreats for England licensed by the justices in 1888, the same number as in 1887. It is significant of the small grip of the evil which this legislation has that so small a number of retreats should meet the demand, and that this does not show much tendency to increase. The inspector, however, is able to report an increase in the number of patients admitted, in 1888 it being 99 as against 66 in the previous year. The admissions were distributed as follows:—Colman-hill House, near Halesowen, 19; Dalrymple House, Ricksmansworth, 16; High-shot House, Twickenham, 13; Montague House, Brook-green, Hammersmith, 10; Old Park Hall, Walsall, 10; Tower House, Westgate-on-Sea, 31; Amesbury House, Amesbury, none. It is gratifying to find an increase of 33 in the admissions, though we must all admit that 99 is a very inadequate proportion of the inebriates of England, for whose recovery the only reasonable chance is to be found in the discipline of institutions of the kind we have named; and, judging from the tenor of the reports from the licensees of the retreats which the inspector gives in his report, it is clear that most of them are of opinion that legislation will have to go much further than it has done if much good is to be effected for this most pitiable class. Liberty is one of our idols; but the liberty of an habitual drunkard is a very questionable and limited quantity. How can the word be applied to a human being without the slightest power to resist taking that which he knows is ruining his business, and destroying all the finest tissues in his body, brain-cells, and liver-cells, and kidney-tubes. Parliament has just passed an Act which asserts that the liberty of an

Digitized by Google

infected person shall not secure him from having his case reported to public authorities who have the power by other Acts to require his confinement under strict conditions of isolation. But the liberty of an habitual drunkard is still so far sacred that, apart from his own consent, he is not to be restrained in the use of alcohol, though it be apparent to everyone that he is not a free agent in regard to it, and in spite of the probability that his indulgence in it will bring him and his family ere long as a burden on to the rates. Parliament has no such compunctions about persons affected with other kinds of unsoundness of mind, and in the era of social legislation which is said to be setting in, when the great miseries which ruin families and individuals will have to be considered, this class of cases will have to be met by something more than the miserable legislation which requires the assent of an habitual drunkard to his own proper treatment. There are only two objections of any force to the improvement in legislation demanded by those who study these cases, and to the introduction of the principle of compulsion. One is the interference with personal liberty, with which we have dealt already. It does not exist in the real habitual drunkard. It is gone, and such legislation is an attempt to recover it. Let any reasonable precautions be taken to verify that it is so. Let magistrates as well as medical men be required for this verification. But thereafter facts should be accepted, and the habitual drunkard treated in a serious manner. The other objection is the length of time required for treatment, and the costliness of interference with liberty for such a time. The answer to that is this—that the precautions we presuppose would exclude all but very real cases. The alternative in most such cases to proper treatment is ruin and pauperism at a still greater cost to the parish or the State. And we should expect this further advantage from a strong compulsory measure — that the very dread of it would operate beneficially in a large number of cases before they reached an extreme form, and prevent the occurrence of such a stage. With these views we endorse the statement of the licensee of the Hammersmith Retreat, who says: "I cannot help wishing that more could be done in the way of legislation, as it is often impossible to induce those really the most in need of control to enter a retreat." The work of Dr. DALRYMPLE, Dr. CAMERON, and others will remain unaccomplished till such legislation is obtained.

OF the many studies pursued by the busy medical practitioner, medical geography seems to offer the greatest variety as regards the subjects it embraces; and as a change of work often acts as a rest and a recreation, so do these many subjects offer frequent opportunities of the main investigation being constantly pursued with little chance of the student being wearied by sameness or fatigued by monotony. Medical climatology, which is a necessary part of medical geography, is in itself a comprehensive branch of science, embracing as it does not only the study of the great factors of general climate, but the almost innumerable phenomena of the minor factors which share in the formation of local climates, so important in relation to disease and its geographical distribution. We all know that the physical configuration and the geological structure of a district greatly influence its local climates, not merely physically and chemically, but in a variety of ways, the intricacies of which require investigation on the spot before their functions can be known. A single instance will suffice: without local knowledge it would be impossible to appreciate the effect of aspect, soil, and subsoil, of solar and terrestrial radiation, or of the rainfall and atmospheric currents, in determining the specific forms that characterise the local flora, indigenous and cultivated alike. The flora of a district is the most faithful and reliable exponent of its local climate, far surpassing in delicacy the most delicate of meteorological instruments. Whoever would study medical geography must be familiar with plant life, the soil in which plants grow and thrive, the rock-base supporting that soil, and the aspects of the land where these ornaments of nature enjoy perfect health, as evidenced by their form, colour, and vigour. In the pursuit of this delightful part of the medical geographer's work, he may leave behind him for a while vital statistics and other severer studies, and whilst enjoying his vacation rambles gather fresh stores of facts amidst the beauties of the lakes, the mountains, the dales, and the sea-shores of his country, the collection of which will tend not only to create a fresh interest in natural history, but enhance the pleasures of his wanderings and their healthful influence on his mind and body.

We have been led to these remarks by an article which appears in our columns to-day on the "Infrequency of Cancer among Females in the English Lake District," by Mr. ALFRED HAVILAND, as a supplement to his former articles published in THE LANCET last year on the "Distribution of Cancerous Diseases in the British Isles." Mr. HAVILAND has been engaged in this investigation for more than twenty years, and each fresh addition to the facts that he made public in 1868 seems to corroborate the propositions he then laid down. The author has always avowed himself to be no theorist, but simply a collector of facts relating to the distribution of disease in this country, and to these disease-facts he adds those pertaining to the several factors of local climates. Whilst acting in this capacity, he claims, however, the right to place certain constantly recurring coincident facts together, and leaves his readers to draw their own conclusions. In this way some highly interesting and important suggestions are placed at the disposal of those who make the natural history of disease their study. And the practical outcome of such investigations is evident; for at a time, when all are seeking health and sites for homes some guide is required, the questions which are at the bottom of the search not being at present easily answered either by the medical profession or by scientists generally. A large sum of money has, however, been paid by the public for the collection of the disease-facts, and for making them known by means of reports. These facts have never been utilised until now in such a manner as to show their distribution throughout the country side by side with those connected with local climates, local geology, and local configuration of land.

The facts connected with the English lake district will be interesting to the dwellers in that delightful part of England, as well as to those who either have visited it, or are about to enjoy its beauties.

Annotations.

"Ne quid nimis."

ARMY MEDICAL OFFICERS.

THE Army Orders of Sept. 1st promulgate a Royal Warrant amending in certain respects the regulations relating to the retirement of officers. It contains an important modification of the rules affecting the pay of medical officers placed on the retired list at their own request. "An officer of our Medical Staff who on voluntary retirement has served for less than three years in the rank from which he retires shall be only entitled to the gratuity or retired pay assigned to the next lower rank." This Warrant appears to have anticipated the recommendation of Lord Camperdown's committee that "a certain term of service should be required from officers after promotion to a higher rank before they are permitted to retire upon the rates attaching to the higher rank, except in cases of permanent ill-health contracted in and by the service." From the short time which has elapsed since the presentation of the report, we can hardly suppose that the regulation has been adopted in consequence of it, but it is satisfactory to find that it is in accord with it. It gets rid of the absurdity of selecting officers for promotion on account of their special fitness for administrative duties, and then permitting them to retire on the higher rate of pension attached to the rank before they have for any reasonable time discharged those duties for which they were specially selected. The regulation does not apply to officers under the rank of brigade-surgeon, nor does it affect any who are retired on account of ill-health, or of having attained the age laid down by regulation for compulsory retirement.

BRAIN FUNCTION AND HUMAN CHARACTER.

IN a paper read before the Anthropological Section of the British Association, Mr. Bernard Hollander of Vienna brings forward some interesting observations on the possible connexion between the areas allotted to various brain functions and the evidences of human character. He draws a suggestive parallel between the conclusions of Ferrier and other geographers of the cortex cerebri and the less exact investigations of the early phrenologists. He reminds us, for example, that the territory assigned as the source of the facial nerve (the ascending parietal and mid-frontal convolutions) nearly coincides with the position of Gall's "organ of mimicry." A similar agreement exists between the supposed centre for taste in the temporo-sphenoidal lobe and the organ of "gustativeness"; between that for mental attention (the first occipital convolution) and Combe's area of "concentrativeness"; that for the facial elevators (the posterior frontal area) and imagination; for the platysma, "the muscle of fright" (ascending parietal) and Gall's apprehension area; for angry expression (superior temporo-sphenoidal) and destructiveness. The parallel here drawn certainly wears an aspect suggestive of reality. At the same time, however, we must receive it with a considerable degree of caution. It must not be forgotten that the question of brain localisation has two sides. What the localisers, on the one hand, take for solid ground, Goltz has, after careful examination, pronounced to be only a mirage. The functions located in a given area, according to him, are easily assumed by another, as if they were due in each case merely to a transient excitation of the will. It behoves us, therefore, to accept with reserve even such attractive coincidences as those above mentioned; though the mere fact of their independent recognition by observers in little or nothing allied to each other should at least obtain for them what Mr. Hollander asks—a fair consideration.

EDINBURGH AND THE UNIVERSITY EXTENSION SCHEME.

FOLLOWING the successful example set by Oxford, the University of Edinburgh has arranged for a series of summer gatherings, which will be inaugurated by a conversazione to be held in the Museum of the Science of Art on Tuesday, the 24th inst., and will conclude on Friday. Oct. 5th. The fortnight's programme will be a varied and interesting one, consisting of courses of lectures by eminent professors and scientists, together with excursions, conversaziones, social entertainments, &c. Amongst the forty or so lecturers may be mentioned the following University professors—Messrs. Baldwin Brown, Crum Brown, Calderwood, Cossar Ewart, Ewing, Geddes, Geikie, Haycraft, Kirkpatrick, Mackinnon, Masson, Nicholson, Steggall, and Tait; whilst Lord Moncreiff and others are also set down for one or more lectures. The subjects treated will come under the headings of Physical Science, Biological Science, History and Ethics, Political and Economic Science, Literature and Art, Music, and Elocution; whilst the lectures themselves, numbering over fifty, will cover a very wide ground. The recreative portion of the programme will include excursions to places of historical, artistic, and scientific interest in and near Edinburgh—all personally conducted by gentlemen qualified to explain the beauties and peculiarities of the particular place visited. In addition, several gentlemen have expressed a desire to invite to social entertainment at their residences those who attend the gathering. The price of tickets for the whole fortnight's gathering seems almost absurdly small—viz., 10*s.* 6*d.*, ranging down to as low as 2*s.* 6*d.* for those who are only able to attend during a portion of the fortnight. Tickets and full information can be obtained from the secretaries, David Philip, S.S.C., and John Arthur Thomson, M.A., 41, Charlotte-square, Edinburgh. The University gathering has been good-humouredly described as "Education by Picnic." Whilst we may believe it to be an effective, we cannot possibly doubt its being a pleasant, way of making good one's educational deficiencies.

THE EMOLUMENTS OF GENERAL PRACTICE.

IT is very easy for junior practitioners to fall into the error of over-estimating the value of practice in general, or of a particular practice with which they may happen to have some acquaintance, by making rough calculations based on the amount of work done in a day and the value of each item as put down in the various medical tariffs that have been published, or as mentioned in a general way as the usual charges of the particular practice in question. Thus, to take a rough example. The average number of visits paid per diem is sixteen, a dozen patients are seen in the surgery, there are fifty midwifery cases a year, and there are some clubs which bring in £40. If the visits averaged 4*s.*, the surgery patients 2*s.* 6*d*, and the confinements £2 2*s.*, the practice would be worth almost £1500, and could probably be worked even in the busiest times, when the visits per diem might be expected to reach to twenty-five or even thirty a day, without an assistant; it is, in fact, exactly the sort of practice which most men would like to have. Doubtless such practices exist, but they are few and far between, and the young man fresh from the hospital who expects to be able either to buy or to make such a one will run a very great chance of being disappointed. In a practice implying the amount of work mentioned, it would probably be found that four of the visits were either paid to club patients or to obstetric cases; that two more were paid to persons for charity or for some other reason which prevented them being remunerative; that the remaining ten, instead of averaging 4*s.*, would not average more than 3*s.*; that eight

Digitized by Google

out of the twelve surgery cases were unremunerative, and that the other four paid only 1*s.* 6*d.* each. The midwifery, again, would probably not average more than £1 11*s.* 6*d.*, and the bad debts would be very moderately computed at 10 per cent. Added to all this, there must be taken into account the fact that, in most practices, a good many of the patients, while able and willing to pay 2*s.* or 2*s.* 6*d.* a visit during a short attendance, are utterly unable to meet a bill of from £7 to £8, such as would necessarily be run up by attendance in the course of a long and serious illness, and these, therefore, have to be charged, say, £2 or £2 10*s.*, or some such sum as may be supposed to lie within their means, however long the attendance may have been. These considerations and corrections will be found to have brought the actual yearly income of the supposed practice down to about £700, and it is by no means a bad representative of a practice of that amount. At all events, we will venture to say that it is a much more common type than the utopian example given above. Beginners who make their bills out by the published tariffs not unfrequently find that, valuable as these documents are in the hands of experienced practitioners, they are apt to prove pitfalls if relied on too absolutely. Artisans cannot pay 2*s.* 6*d.* a visit for long, however small a house they live in; and tradespeople who live in £50 houses will very frequently show a practitioner the door if he charges them anything like 5*s.* a visit. Again, mercantile and professional people will rarely pay 7*s.*, even if they do live in £100 houses. In how many practices, too, are surgery patients charged 1*s.*, or indeed any smaller sum which they seem willing to pay; and how often, from the stress of competition, is midwifery taken at 15*s.*, or even at 10*s.* or less. These little matters are not always thought worthy of mention in the tariffs, as the system of low fees is not to be commended; but they should, nevertheless, not be ignored by a young and inexperienced man who is commencing.

LEPROSY IN BRITISH GUIANA.

WRITING in *Timehri*, the journal of the Royal Agricultural and Commercial Society of British Guiana (June 1889), Mr. J. D. Hilles, F.R.C.S., says that to the most casual observer the increase of leprosy in Demerara must be apparent, that the asylum cannot be enlarged fast enough to contain the cases seeking admission, and that the increase has been greatest in the last decade. The earliest accounts point to the disease having been introduced into the colony by slaves from Africa, and the colonists took measures to isolate them. But, as a result of immigration, leprosy was introduced from India in 1842 and 1858, and from China in 1861 and 1862. In 1831 there were some 431 leper *negroes* in Demerara; at the present time, says Mr. Hilles, "it is calculated that there must be more than 1000 cases of leprosy here, or 1 in every 250 of the population, and this notwithstanding the large number that die annually from the disease—over 16 per cent." He relates how an Indian tribe—the Warrans—which 50 years ago was brought into contact with the leper colony, became infected with the disease, no other tribe having it. He also points out that leprosy occurs in largest amount in the vicinity of the Leper Asylum than elsewhere. So that Mr. Hilles is convinced the disease is communicable—(1) by intermarriage or cohabitation, and (2) by inoculation or contact. In dealing with each of these points, he states that the late Dr. Gavin Milroy, who was chiefly responsible for the report of the Royal College of Physicians in 1867, paid a short visit to the West Indies, but had not time to make himself acquainted with both sides of the question. In more than one instance he says that Dr. Milroy was misled. In Mr. Hilles' own experience, he has seen cases which had undoubtedly arisen by contagion. British Guiana now possesses well-appointed Leper Asylums, each with a resident medical superintendent. But the difficulty is to prevent the inmates absconding. Mr. Hilles thinks that it is not too much to ask them to submit voluntarily to strict segregation—the only arrangement at all likely to stamp out the disease. But he thinks that the West Indies should combine and form a large leper community in an island (e.g., of the Caribean Sea), and by insisting on strict isolation succeed in eradicating the disease.

THE BACILLI OF CHOLERA, TYPHOID FEVER, AND TUBERCULOSIS IN MILK, BUTTER, AND CHEESE.

THE experiments of Dr. L. Heim in the laboratory of the German Imperial Health Department on the vitality of germs in certain kinds of nutriment, have led to the following results: In non-sterilised new milk the germs of cholera bacillus remain as long as the milk has not become very acid. A somewhat high temperature, which accelerates the acidity, accelerates the destruction of cholera bacilli. Occasionally they could be seen for two or three days even in acid milk. Their extreme vitality was six days. In butter they could in favourable circumstances live a month; but in butter that had become caseous and in cheese-curds they could barely live a day. The bacilli of typhoid fever had a much greater power of resistance in milk; in non-sterilised milk which had become acid, they were still visible after twenty-one and thirty-five days, but could not be found at the end of forty-eight days; in butter their vitality lasted three weeks; in whey and natural cheese, only three days. Milk which contains tubercle bacilli may produce the disease. These bacilli may live for three days in decomposing substances. Milk to which tubercle bacilli had been added was after ten days still infectious, but not so in four weeks, especially if decomposition had taken place in the meantime. In butter the vitality of tubercle bacilli lasted four weeks. In whey and cheese they were able to communicate the disease for a fortnight, and they remained visible for thirty-two days.

A CRY AGAINST CYCLISTS.

THE *Ladies' Pictorial* has issued a bitter and angry cry against the world of cyclists, on the ground that the cyclist is a public danger to the pedestrian traveller and a danger also to himself. "The medical profession," adds our contemporary, "can testify to the danger of cycling, yet it goes on unchecked by tax, by the common sense of those seeking recreation, or by public opinion, which is so often clamorously expressed against a far less grave nuisance and danger." This is indeed a grave charge, but we are happy and generous enough to say that an appeal to the profession of medicine would hardly bear out the statement of danger which the writer above quoted assumes. There are dangers from the excessive race riding and what is called "record breaking" of cyclists; dangers we were amongst the first to point out, and which our good friend *Mr. Punch* has lately most amusingly, and not one bit too severely, criticised. But these dangers are confined to a peculiar and, we are glad to think, very limited class of young enthusiasts, who, full—too full—of energy, want to carry all before them, to beat the horse out and out, and to come in little less than second best with the penny-a-mile train. When this is admitted and deplored by all true friends of the art of cycling, the worst is told, in so far as the medical profession can tell; for, probably, of all strong exercises this is the one which, considering the vast numbers who carry it out, either for recreation or for business, brings the smallest amount of grist to the professional mill. Even in hospital practice it is astonishing to observe how very few cases of accident

Digitized by Google

from the cycle are brought in—a fact the more remarkable when we recall the crowded streets through which the wayfarers, on two or three wheels, wend their course. Whether it may be advisable to make the law more stringent than it now is against cyclists is a question which may have to be reconsidered. The cyclists themselves consider that already the regulations under which they are placed, and the restrictions which apply to them, are too severe, and they would resist, we may be sure, any attempt to lay a tax on them. As to the attempt to suppress them by any arbitrary measures, the very idea is absurd. A mode of locomotion which gives to man twice the rapidity of progress on foot could no more be prevented, now that it has been established, than the use of carts and carriages.

RECURRENCE OF CANCER OF THE BREAST AFTER AMPUTATION.

FROM microscopic examinations of carcinomatous mammæ amputated by Professor Küster, Dr. Heidenhain predicted a return of the cancer in twelve cases, because parts of the morbid growth had remained in the wound. In the other cases he diagnosed a radical cure, which diagnosis had proved correct up to the date of the publication of his paper, because the operation had removed the whole of the morbid growth. The usual cause of the recurrence is that only microscopic parts of the gland or the tumour remain on the surface of the pectoralis major. In thin women the whole mamma is firmly attached to the muscle, but in obese subjects small glandular lobules are generally attached to the fascia between the mamma and the muscle, so that in amputation above the muscle small particles of the gland may easily be left. Every mamma in which a single cancer node is found, according to Heidenhain, is largely, perhaps *in toto*, diseased. He found the epithelial cells of the acini proliferating in all parts of the mamma, and observed hypertrophy of the peri-acinous connective tissue, and he believes that these acini remaining in the wound form the origin of late secondary growths. In the retro-mammary fat there are, side by side with the bloodvessels, lymphatics leading from the mamma to the subjacent fascia, and the latter were, in two-thirds of the cases, full of metastatic cancerous masses. The pectoralis major itself is only affected when a metastatic cancer-node invades the muscle from the fascia, or the original tumour attacks it by its own simple growth. Heidenhain concludes that, to make amputation of the mamma more successful, it is necessary, even in freely movable carcinomata, not only to remove the whole mamma, but also a superficial layer from the whole of the pectoralis major, and, in tumours which are closely connected with the muscle, to entirely extirpate the latter.

SOUTH AFRICAN PRACTICE.

SOME excellent advice to those who propose to practise in South Africa is given in the last number of the *South African Medical Journal*—advice which applies equally well to other colonies. First of all, the immense importance of clinical training in a school where there is abundance of material, as in London or Vienna, is insisted on, as the colonial practitioner, having no consultants to apply to, must himself be equal to all emergencies. An assistancy for six months to a general practitioner at home is also recommended, in order to learn how to treat those slight ailments which form so large a proportion of private practice, and how to study the foibles of patients and the principles and practice of medical ethics. Again, after landing, it is most advisable to take a post as *locum tenens* before settling, in order to gain experience as to the ins and outs of colonial practice, and to have time to make up one's mind as to where to settle. The difficulty of gaining accurate information about a field of practice is extremely great, the solicitations of local residents and their magniloquent delineations of the openings and opportunities for practice not being to be trusted in the least. A man must judge for himself, and he can only do this by gaining experience in South African practice. "Then, again," pursues the *South African Medical Journal*, "and this is to the young men—do drop the *Veni, vidi, vici* style so common in new arrivals. It will be knocked out of you by-and-by in any case, and for the honour of your profession and for the sake of good fellowship with your fellow practitioners, doff it at once. Half the dissensions between established practitioners and new beginners result, not from what the latter do, but from the irritating way they do it. Never neglect the minor morality of professional life—etiquette. This, read between the lines of professional routine, may be described as a code of laws designed to secure the greatest good for the greatest number. If you are settling in a town where there are already *confrères*, call on each and everyone before you prescribe for a patient. Ascertain their fees and mode of doing practice, and conform thereunto as closely as possible. Then in all respects begin as you intend going on. If you intend doing your own book-keeping, do it from the beginning; if you mean to place it in the hands of an agent, commence that course concurrently with practice. The same rule applies to the decision between quarterly or annual accounts, between abridged or detailed bills, between charging on medicine or not. Changes in any of these respects invariably irritate patients. And, lastly, make up your mind to pursue your practice with an honourable professional ideal always before you, and never allow yourself to be tempted into the devious by-ways so common in South African life."

THE ETIOLOGY OF GOITRE.

THE causation of endemic goitre has for a very long time excited the interest of physicians and surgeons, and many investigations have been made into the soil, the water, the air, the habits, and the food of those dwelling in goitrous regions. But it cannot be said that the matter has been cleared up, or that we have advanced much from the position our forefathers held a century or even centuries ago. Dr. Th. Kocher of Berne, who has a great reputation for the successful excision of enlarged thyroid bodies, and who was the first to point out and to establish the ill results of complete removal of the thyroid body in children and adolescents, has recently conducted some careful investigations into the causation of this disease. He first of all determined accurately in what parts of his own canton goitre was common. On comparing the water of these regions with that of goitre-free neighbourhoods, he finds that the one striking difference is that where goitre is abundant the water contains a considerable quantity of organic or organised material, and he concludes that it is this factor which determines the prevalence of goitre in any district. He finds that in certain goitrous parts particular families who have access to special water-supplies in which there is not this quantity of organic matter remain free from goitre, although breathing the same air, living on the same soil, engaging in the same occupations, and eating the same food as their very goitrous neighbours. On comparing the chemical composition of goitrous and non-goitrous water in the Berne canton, the only other difference he found was that the quantity of sulphate of lime was less in the goitrous; but, as it is well known that goitre is often found in those who drink water richly laden with this salt, this difference cannot explain the great pathological fact. Dr. Tovel has found that the water in goitre-free parts contains a very minute quantity of mitro-organisms. And it has further been shown that if goitrous water is injected into rabbits the thyroid gland is very

Digitized by Google

prone to swell, although in dogs the injections have no effect. Kocher's investigations do not certainly completely clear up this difficult subject, but they throw some light upon it, and as such are to be heartily welcomed.

DIABETES MELLITUS AFTER EXTIRPATION OF THE PANCREAS.

DRS. V. MERING and O. MINKOWSKI report a large number of experiments from their laboratory at Strasburg, all showing that extirpation of the pancreas results in true diabetes mellitus with all its ordinary symptoms. A dog whose pancreas had been removed secreted after forty-eight hours' fasting from 5 to 6 per cent. of sugar in his urine. Another dog weighing 15 lb. secreted under an exclusive meat diet two pints of urine daily, with 6 to 8 per cent. of sugar. Introduction of grape sugar into the food resulted in an increase of this by 6 per cent., by far the greatest part of the grape sugar being excreted without having undergone any modification. The urine also contained appreciable quantities of "acetone." The percentage of sugar in the blood was likewise much increased, being in one case 0·30, in another 0·46. Glycogen at the same time disappeared altogether. In a dog, for instance, which had been diabetic for four weeks, and which was killed while being fed on full flesh diet, neither liver nor muscle contained glycogen. Transfusion from a diabetic dog caused no secretion of sugar in a healthy dog.

RAILWAY AMBULANCE.

THE ambulance movement is universally accepted as one of the most useful influences called into action by the spirit of social reform. It has gathered its promoters and assistants from every class, and there can be no doubt that it has in a multitude of cases minimised, if not removed, the danger primarily arising out of sudden illness or injury. The history of its past achievements fully justifies the claim put forward a few days ago by Mr. Waynman Dixon for a further great extension of its operations. This is no less than the formation of an efficient corps of railway ambulance men. First aid, Mr. Dixon reminds us, is now to a large extent available in case of need in the mining districts, while throughout our extensive railway system, where the danger of accident is hardly if at all less, the means of skilled and ready help are hardly to be found. It is not alone for the rare occasions of great disaster, but even more for the succour of numerous isolated cases of injury, that he now proposes to recruit the ranks of the modern hospitallers. In this connexion it will be profitable to note that during last year the number of fatal accidents on railway lines amounted to 1 per 807 men employed, and of injuries more or less serious, but not fatal, to 1 in 157. The help required is of two kinds, intelligent and material. The latter would be represented by simple apparatus, a few bandages, slings, and the like to be placed in the guard's van of each train; the former by the necessary instruction of *employés*. This could not be more efficiently carried out than it now is by means of voluntary instructors, and for this purpose it is needless, as Mr. Dixon says, to seek for better methods or machinery than those afforded by the St. John Ambulance Association. The cost of training would be trifling. It is estimated that an annual payment of sixpence per man would suffice to educate 5 per cent. of the *employés* annually. An entrance fee of another sixpence might be required to launch the undertaking. In consideration of the end in view, its practical effect as a form of workmen's insurance, its utility to passengers, and the probability of its diminishing the accident claims now paid by the companies, the project is equally worthy of its modest maintenance at the hands of the men and their masters, while the travelling public may reasonably assist it with at least an occasional *douceur*. Workmen in other callings have shown much interest and even enthusiasm in ambulance training. The railway men might safely be relied upon to show an equal willingness to learn; and this means much towards ultimate success. Apparatus are most useful, but knowledge of what to do is the first necessity. The former may in emergencies be extemporised; the latter must be stored before it is available for work.

DR. VON NUSSBAUM'S JUBILEE.

A KINDLY TRAIT of professional life among our Teutonic kinsmen is their punctual observance of the jubilee days of those who have done them service or honour in the practice or teaching of the medical art. Hardly a month passes without some such display of pious feeling on the part of the younger generation towards those whose day is far spent. Privy Councillor Dr. von Nussbaum is the latest recipient of the jubilee congratulations of old pupils, patients, and friends, and his noble career sufficiently explains the cordiality of the celebrants and the world-wide extent of their participation. He was born at Munich in 1829, and having selected medicine, especially its surgical department, as his profession, he qualified so brilliantly for it in his undergraduate years that in 1852 he was appointed assistant in the surgical wards of the General Hospital at Munich, graduated in 1857, became member of the teaching staff of the same University, and in 1860 was made Professor in Ordinary of the Surgical Clinique. It was in 1870–71, however, that he most distinguished himself, and his self-sacrificing devotion to the wounded in the sanguinary campaign of that period, the skill and success of his operations, often performed under fire, and his contributions, under circumstances the most trying, to the efficiency of the field ambulance department, will form a bright page in the medico-military annals of our century. The attainment of his sixtieth birthday was the occasion that evoked the loyal, the well nigh filial demonstration of the 2nd inst., and the messages by telegram and letter, often from far beyond sea and from either hemisphere, the laurel wreaths, the bouquets, and addresses that greeted him on the morning of that day must have been to him recompense more than sufficient for his life-work. Except for the injury to the lower extremities, contracted in the Franco-German war, Dr. von Nussbaum enjoys the soundest health and vigour of all his faculties, physical and mental, and, as in 1880, when he celebrated his Doctor-jubilee, so now, on the festive recurrence of his sixtieth birthday, there is every prospect that many years of beneficent activity are yet in store for him, whether in the operating theatre or in the surgical wards, whether in the academic chair or in the Privy Council chamber.

FEVER IN LONDON.

THE autumnal increase of scarlet fever is engaging the attention of the Metropolitan Asylums Board, who have found that the accommodation in the hospitals now occupied is likely to be insufficient for the wants of London. It has therefore been determined to prepare the Northern Hospital for occupation by convalescents. The managers were not unanimous on this point, the opinion being held by some that the South-Western Hospital should be opened for acute cases. The Northern Hospital will so far relieve the other institutions that it may be hoped it will meet all the requirements of the managers. It may be anticipated, however, that the cases will increase in number until the end of October, and it is possible that the South-Western Hospital will be required later. No anticipations can be formed as to the effect a new Notification Act may have in

Digitized by Google

throwing work upon the managers; that it will lead to an increased demand for hospital accommodation, however, is a certainty, but to what extent experience only can show.

ABNORMAL OR CONTRARY EFFECTS OF ANTIPYRETICS.

PROFESSOR S. E. HEUCHEN, of Upsala, has frequently observed in the academical hospital the so-called contrary effect of antipyretics, mostly of chinolin, but also of antipyrin, antifebrin, and phenacetin. He believes the increase of temperature on administering these drugs to be due to a variety of causes. In some of his observations there might have been a spontaneous rise of temperature, while in others the symptom is explained as being due to an irritation communicated from certain parts of the body. Professor Heuchen mentions several cases in which the administration of chinolin resulted in vomiting or diarrhœa. In these, however, the doses had been large enough to be considered toxic. A similar explanation is suggested of a case mentioned by Laache, in which an extensive rash was produced, the temperature sank, and the patient became collapsed. A rash was observed by Heuchen only in cases in which chinolin had no abnormal action on the temperature. The best explanation of this singular occurrence is, however, probably to be found in the observation of Geigel of Würzburg, who states that on administering antipyrin or antifebrin the temperature always first rises and then rapidly falls upon the appearance of diaphoresis. He thinks that in those cases in which the diaphoresis is slow in appearing the rise in temperature has probably also lasted longer, so that this contrary effect is due solely to the absence of diaphoresis.

LUMBAR CHOLECYSTOTOMY.

IN March, 1885, Mr. Wright of Manchester recorded in our columns a case in which, after an exploration of the right kidney for stone with a negative result, an enlarged gall-bladder was opened through the same (lumbar) incision, and a large stone removed from its interior. Dr. Mears of Philadelphia has recently had a somewhat similar experience, which is published in the last volume of the Transactions of the American Surgical Association. The patient was a woman twenty-nine years of age, who was admitted to hospital for the operation of nephrorraphy. She was found to have a rounded tumour, about the size of the kidney, lying a little to the right of the middle line and at the junction of the umbilical and hypogastric regions. This tumour was freely movable in all directions. A vertical lumbar incision was made, the right kidney exposed, and its capsule divided and stitched to the edges of the wound. The tumour was uninfluenced by this procedure, for, pressing it towards the loin, it was made to bulge in the wound covered by parietal peritoneum. The serous covering was divided, and then the nature of the tumour—a distended gall-bladder—was clearly recognised. The fundus was incised, and a gall-stone was found impacted in the cystic duct. As it was impossible to extract the stone, it was crushed *in situ*, and the fragments were pushed on into the intestine, "the freedom of the passage being announced by the passage of intestinal gas." The patient made a perfect recovery. The case is interesting rather as a warning than as a guide. There is no advantage in opening the gall-bladder in the loin; on the other hand, there are serious disadvantages in doing so. The case is a good example of the drawbacks of the lumbar incision in those instances in which the nature of the case is doubtful. Had an abdominal exploration been made, the nature of the tumour would have been at once apparent, and the treatment would have been carried out in the most advantageous manner.

A RESCUE RACE.

AT the regatta at Bognor on the 31st. ult. there was a new kind of race, having for its intention the encouragement of the art of saving life at sea, and called "The Rescue Race." The idea of it was suggested, and the plan for it arranged, by Dr. B. W. Richardson, who is resting for a few weeks at Bognor from professional work, and the competition, carried out by the boatmen with great spirit and skill, excited much enthusiasm. The arrangements of the race consisted in casting a number of dummies, each the size of a human body, into the sea, about 200 yards from land, as if they had been persons capsised from a boat and were drowning. At the signal of distress, the boats lying on the shore, each boat containing two men, were pushed rapidly into the sea, and rowed with all speed to the scene of supposed peril. On reaching the spot, one man in the boat had to leap into the sea, seize one of the floating bodies, get it into the boat, and with his comrade return to land as fast as possible. The boat which first reached the shore and placed its burden safely on dry land took the first prize, and so on in order of arrival for two other prizes. Another competition having the same object was carried out by two of the bathing-women, without boats, their skill being demonstrated by swimming. The prizes, amounting to seven guineas, were contributed by Dr. Richardson and his friends, and with other regatta prizes were presented to the successful candidates in the evening by the Rev. Dr. Conder, chairman of the local board. Such a rescue race might be made a prominent feature at every regatta.

CHOLERA.

A TELEGRAM from Athens, dated Sept. 11th, states that according to intelligence received from Constantinople some cases of cholera had occurred in the latter city. Cholera is raging at Basrah (or Bassora), a city in direct river communication with Bagdad, where a severe epidemic of cholera also prevails, and where, according to Mr. F. D. Mocatta, there is a population of 26,000 Jews, who have been thrown into a state of great destitution, and who are without resources for burying the dead. As direct steamer communication exists between Bombay and Basrah, it is to be hoped that the authorities at the latter place will leave nothing undone to stamp out the epidemic. A melancholy interest will attach to the receipt in London from Basrah of a telegram, the simple and telegraphic brevity of which tells its mournful tale perhaps more eloquently than many words. The telegram in question runs thus:—"On the 16th Aug., at H.B.M.'s Consulate, Basrah, Persian Gulf, of cholera, Eric Charles, aged three years and a half; on the 18th, Maude Elma, aged five years and two months, only children of Patrick and Ethel Robertson; and, on the 21st Aug., Patrick J. C. Robertson, H.B.M.'s Political Agent and Consul, aged forty-two."

THE MILK TRADE.

IN a recent address delivered by Mr. S. W. North, medical officer of health to the city of York, to the National Association of Sanitary Inspectors, the subject chosen was the Milk Trade as affecting Public Health. The various diseases which have been communicated to man through the agency of milk were considered; but special stress was laid upon the question of the production of human tubercle as the result of the ingestion of the milk of tuberculous cows. It was contended that the same defective hygienic conditions which favour the development of this disease in man also favour its production in animals. Thus, deficient light and air, dampness of sheds, overcrowding, imperfect

Digitized by Google

ventilation, bad and insufficient food, and filthy surroundings were set forth as the conditions tending to lower health, to impair nutrition, and to increase susceptibility to tuberculosis both in man and in the cow; and all dairy-farmers, as well as those responsible for the administration of dairies, would do well to give heed to the warning which these facts convey. Amongst the remedies which Mr. North would suggest are a careful and systematic inspection of dairies and cattle by competent persons, and the requirement that all who sell milk within the area of a sanitary authority should possess a special licence granted by that authority, and capable of being withdrawn or suspended whenever sufficient reason exists for such action. It was further proposed that every producer and vendor of milk should be bound to report to such sanitary authority the occurrence of any disease amongst the cattle, or the persons of his household, or amongst those engaged in the preparation or distribution of the milk. Such an address cannot fail to lead to a more careful and intelligent performance of some of the more important duties devolving on sanitary inspectors.

INSANITARY AREAS IN CLERKENWELL.

IT is stated that Dr. Griffith, the medical officer of health for Clerkenwell, has made representations to the London County Council of no fewer than fourteen localities which, in his opinion, are insanitary, and should be done away with. The newly-appointed authority are likely to have their hands full, and it will need some nice discrimination to distinguish between demolition which should be undertaken by the vestries and district boards, and for which under Torrens' Act no compensation is given, and the improvement of sanitary areas which can only be effected by the London County Council under Cross's Act at considerable public expense. We trust the ratepayers will not begrudge the cost of the removal of these plague spots from London. It cannot be expected that the errors of the past can be undone without some burden being cast upon the present inhabitants of the metropolis, but it behoves the Council to see that we in our time are not guilty of mistakes that a future generation will have to redeem, for London must have spent in health improvements already not far short of two millions, in addition to the amounts which have been expended by private householders.

HOMICIDAL EPILEPSY.

AFTER recent expositions of this terrible malady, particularly after Lombroso's classic description of "epilessia sanguinaria," superintendents of continental infirmaries, one would think, might show greater circumspection in harbouring epileptics of apparently the harmless kind than seems to have been the case at Lovendegem, some two leagues from Ghent. Into the hospital there a Belgian, thirty-five years of age, had been admitted, suffering from epilepsy. He was allowed to associate in a common hall with old men mostly incurables, and little boys hopelessly rachitic, the surveillance of this motley assemblage being entrusted to some Sisters of Charity. How unequal these good ladies were to their task is evident from this—that notwithstanding his having shown symptoms of aggressiveness, notwithstanding that he had given vent to the strangest illusions, asserting that Brussels was in flames, that the king had been banished, that at Antwerp he had himself seen carts laden with bombs, and had added, "They have given me lion's flesh to eat; I feel my blood boiling with it," he was left pretty much to himself, and actually entrusted with a razor to shave himself with! On the night between the 29th and 30th ult., he rushed, armed with this weapon, into the hall, which, a sitting- and dining-room by day, was a dormitory by night, and began at once to deal murderous strokes at the sleeping inmates. He had already wounded several of the old men and children, who were too weak or too dazed to defend themselves, when the shrieks and general tumult brought the Sisters to the scene. In vain they tried to disarm him. They only succeeded in getting gravely wounded themselves. Meanwhile one of them sounded the alarm bell, and the madman was shortly thereafter overpowered and pinioned. As soon as practicable, he was conducted, under a strong escort, to Ghent, and there confined in the Guislain Lunatic Asylum, the place to which he should in the first instance have been taken. Twenty-seven is the number of those who were wounded by him, more or less severely, among the most serious cases being that of the Mother Superior, who sustained some deep razor cuts on the head, but nevertheless refused to quit her post till he had been secured. The tragic affair is, indeed, a loud warning to the superintendents of promiscuous hospitals, in which epilepsy is largely represented, never to admit or retain such cases when illusions of the aggressive kind are manifested. For these the well-appointed, thoroughly organised lunatic asylum is the only safe habitat.

ALLEGED INSANITARY STATE OF FROME.

IT appears that some of the leading inhabitants of Frome have appealed to the Local Government Board on account of the stench from the river, which is alleged to have been associated with cases of enteric fever and diarrhœa in Lullington. The chairman of the local board has evidently been deeply pained by this action, and in a speech which he delivered at its last meeting he set forth in some detail the action which had been taken, and which was still in progress, to remove the causes of complaint, and he, in the end, contended that the assertion that the local board declined to undertake the necessary remedial work, was uncalled for. He then resigned his position, and urged other members to do the same, on the plea that the vacancies could then be filled up by a number of the complainants, who were men of means, leisure, and position, and who would thus have an opportunity of displaying their zeal for the sanitary state of the town. Whatever the true state of Frome may be as regards its sewage disposal and other similar matters, no one can well object to the attitude of the chairman as undignified or unmanly.

THE CEREBRAL COMPLICATIONS OF EAR DISEASE.

DR. OTTO KÖRNER of Frankfort points out that all the cerebral complications of ear disease are more frequent on the right than the left side. Thus, of 31 cases of cerebral abscess, 18 occurred on the right side from disease of the right ear, and 12 on the left from disease of the left ear, and in one case there was abscess on both sides following disease of both ears. Similarly, of 61 cases of thrombosis of the lateral sinus, 35 were met with on the right side and 26 on the left. Of 23 cases of meningitis from ear disease, 17 affected the right side and 6 the left. Adding these together, we have a total of 115 cases, of which 70 were on the right side, 44 on the left side, and 1 bilateral. Körner traces this greater frequency on the right side to the fact that the groove for the lateral sinus passes further forwards and outwards into the petrous and mastoid bones on the right than on the left side. The bony wall separating the sinus from the mastoid antrum is therefore thinner on the right side. Added to this is the fact that in brachycephalic skulls the anterior cerebral fossa is considerably nearer the mastoid antrum than in the dolichocephalic. In the former cerebral complications of ear disease more readily ensue than in the latter.

OVERCROWDING OF THE PROFESSIONS IN GERMANY.

PROFESSOR W. LEXIS of Berlin has just published a pamphlet on the undue increase in all the learned professions. The Roman Catholic Theological Faculty alone fails to increase, but all the others do so to a most alarming extent. In medicine, Dr. Lexis considers 2675 the average number of students for the whole of the universities of the German Empire. This number was in 1877–78 reduced to 1774, but this reduction was soon made up, and in 1888–89 there were 2344 over the average. The average number of new licences to practise is, according to Dr. Lexis, 465, which number was not surpassed until 1886. The near future, however, offers most unfavourable prospects, as in proportion to the large increase of students, more than 800 new licences per annum must be expected. The German Association of Teachers in Realschulen had some time ago offered a prize of £50 for the best essay on the following question: "Why are the learned professions overfilled, and how can this evil be remedied?" The prize has now been awarded to two essays out of the seventy-six sent in, which will shortly be published together in book form under the title: "The Eagerness to enter the Learned Professions, and the Causes and Remedies of this Evil," by Fr. Pietzker, Superior Teacher at the Gymnasium of Nordhausen, and P. Freuttein, Professor at the Carlsruhe Gymnasium.

ENTERIC FEVER AT CHINLEY.

ACCORDING to a report by Mr. C. J. Bennett, medical officer of health to the Chapel-en-le-Frith rural sanitary district, enteric fever prevails in the village of Chinley under very aggravated circumstances. Indeed, such is the overcrowding by navvies that in one house thirteen persons were found to be living, of whom five slept in a room where there were enteric fever patients; and in another house, containing two bedrooms, eight persons shared these rooms, each of which was occupied by an enteric fever patient. The need for some temporary accommodation both for the sick and the healthy is a matter calling for immediate action.

POSTERIOR RHINOSCOPY.

THE difficulty of making a satisfactory examination of the naso-pharynx and posterior nares by posterior rhinoscopy is well recognised. In the current number of the *Centralblatt für Chirurgie* Dr. Dorn states that he has had great success in cases of operations in this region by placing the patient with the head hanging vertically back over the end of a table. He states that in this posture it is easy to introduce a mirror into the naso-pharynx and to see every part of it, and to manipulate instruments, such as forceps and snares, under the guidance of the mirror, just as is done in the case of the larynx. The danger of hæmorrhage during operations is greatly diminished when the patient is in this position.

SUCCESSFUL PROSECUTION OF QUACKS.

THE Medical Defence Union are to be congratulated on the success of their latest attempt to put down adventurers who trade upon the weakness of a certain portion of the public. They have brought six summonses against three unqualified practitioners of the "notorious advertising venerealist type" in Birmingham. One of them was C. F. Groom, who at the instance of the Union was struck off the rolls of the College of Surgeons last year. The summonses were taken under the 40th section of the Medical Act for the illegal assumption of a medical title. It is gratifying to learn that the full penalty was inflicted in all the cases, amounting to £124 14*s.* 6*d.* This, we are informed, is only the first stage, as the Defence Union intend to bring exactly similar actions in the County Court, under the Apothecaries Act.

CREASOTE TREATMENT OF PULMONARY TUBERCULOSIS.

DR. BOURGET has for the last three years treated tuberculosis of the lungs with large doses of creasote, thoroughly saturating the system with the drug, and he claims to have obtained most favourable results by his method. He prefers, however, guaiacol, as being less irritating to the stomach and as being therefore better borne than creasote. Dr. Bourget recommends the following prescription, substituting in winter cod-liver oil for the wine: Guaiacol, 2 dr.; tinct. quiniæ, 6 dr.; vin. Malacc., 40 oz. He begins with a tablespoonful at every meal, gradually increasing the dose until three tablespoonfuls are taken. Patients have in this way taken from twenty-two to thirty grains of guaiacol in the day without any trouble. Patients who could not take wine had the following enema administered: Guaiacol, 30 gr.; ol. amygd., 5 dr.; acac. pulv., 2½ dr.; cf. emuls. cui add. aqu., 40 oz.: misce; sig., "For four enemas." In winter Dr. Bourget prescribes: Guaiacol, 40 gr.; ol. jec. as., 6 oz.: misce; sig., "One tablespoonful at every meal." The patient is also rubbed with the following lotion before bedtime, on chest and back and in the axillæ: Creasote e. fag., 5 dr.; ol. jec. asell., 6 oz.: misce. He is then covered over with blankets. During day, and if possible by night also, the patient inhales from two to three drops of creasote by means of a nasal respirator.

STYRONE AS AN ANTISEPTIC.

DR. BEACH, of the Massachusetts General Hospital, says that, having studied the action of styrone (prepared from liquid storax and balsam of Peru) for eleven years, he can confirm the statement he then made as to its antiseptic properties (*Boston Medical and Surgical Journal*, Aug. 1st). It possesses the advantages of being (1) efficient, (2) non-poisonous, and (3) agreeable in odour. It may be used as a deodorant for ulcerating cancers in the form of a spray (styrone, 1 dr.; glycerine, 1 oz.; and water, 1 oz.), or applied to raw surfaces in the form of an emulsion, with olive oil, water, or vaseline. From experiments made by Dr. E. K. Dunham, Bacteriologist to the Massachusetts Board of Health, it is shown that the germicidal powers of styrone are considerable, as the development of such organisms as putrefactive bacteria, cholera bacilli, streptococcus pyogenes, and staphylococcus pyogenes aureus, was checked by certain proportions of styrone.

FOREIGN UNIVERSITY INTELLIGENCE.

Bahia.—Dr. Joaquim M. dos Santos has been appointed Assistant Clinical Professor of Children's Diseases.

Bonn.—Dr. Fritz Noll, assistant in the Botanic Institute in Würzburg, has been appointed Extraordinary Professor of Botany.

Innsbruck.—Dr. W. Roux of Breslau has been appointed to the chair of Anatomy.

Manilla.—It is thought probable that the Spanish Colonial Ministry, which is at present occupying itself with educational matters, will establish a university here.

Pavia.—Dr. E. Pestalozza has been recognised as *privat-docent* in midwifery and gynæcology.

Prague.—Professor Hueppe will commence a course of lectures on Bacteriology at the Hygienic Institute on Oct. 1st. Demonstrations on the same subject will also be held during the winter session.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Jacobsen, Professor of Chemistry in the University of Rostock, at the age of forty-nine.—Dr. Anthon Geuther, Extraordinary Professor of Chemistry in the University of Jena.—Dr. Anton Nuhn, Honorary Professor of Anatomy in the University of Heidelberg, whose name is connected with the glands discovered by him in 1845 in the apex of the tongue. Professor Nuhn was seventy-four years of age, and was, with the exception of Professor Hyrtl of Vienna, the oldest German anatomist.—Dr. Josef Tieftrunk of Prague, formerly body physician to the Emperor of Austria.—Dr. Franz Hellwig, the botanist attached to the German New Guinea expedition.—Dr. Wasseige, Professor of Midwifery in the University of Liège.

THE establishment of a Pasteur Institute at Rome for the prevention and cure of hydrophobia is now, after much friction, *un fait accompli*. The Senatus Academicus has granted the necessary accommodation, laboratories, and other accessories, while Professor Angelo Celli, director of the Hygienic Institute, who successfully started a similar establishment at Palermo, will be the working president. An effective staff of assistants is in course of being provided, so that in a few weeks the sufferers from bites of rabid dogs in Rome and the Agro Romano will be under no necessity of repairing, as heretofore, at the expense of the commune, to the Istituto Antirabbico at Naples.

STATE MEDICINE formed a special feature of the Medical Congress that opened its proceedings on the 1st inst. at Ancona. The Government was represented by the Under Secretary of State for Public Instruction, Signor Mariotti, who in an introductory address pointed to the immense progress Italy had made in hygiene, and gave official assurance that the sanitary reforms initiated under Signor Crispi's government would be energetically carried out. Count Orsi, a veteran hygienist, congratulated the Congress on the substantial aid its predecessors had given to Signor Crispi's policy.

IN Bonn the Geheime Medicinalrath, Professor Hermann Schaafhausen, has just received from his colleagues, students, and fellow-townsmen the honour of a public celebration of his Doctor-jubilee, having graduated at Berlin fifty years ago. Over and above Professor Schaafhausen's special work in the Medical School at Bonn, he has achieved a world-wide reputation in anthropology, the German Anthropological Society owing its origin almost entirely to him. Since 1853 he has been one of the most conspicuous advocates of the "Descendenz-theorie."

PROF. LAWSON TAIT of Birmingham will deliver the annual address, on "Ectopic Gestation," to the members of the Northumberland and Durham Medical Society, in the College of Medicine, Newcastle-on-Tyne, on Oct. 4th, at 6 P.M. The medical profession in the north of England is cordially invited. It is proposed that the members and their friends should dine together after the delivery of the address. Non-members wishing to be present at the dinner should write at once to Dr. Oliver, Newcastle-on-Tyne, the honorary secretary of the Society.

DR. J. S. CAMERON (medical officer of health for Huddersfield), Mr. A. E. Harris (medical officer of health for Sunderland), and Mr. Sweeting (medical superintendent of the Western Fever Hospital, Fulham) are the three candidates for the post of medical officer of health for Leeds. The final selection will be made at the next meeting of the Town Council.

BRITISH PHARMACEUTICAL CONFERENCE.

THE twenty-sixth annual meeting of the British Pharmaceutical Conference was held at Newcastle-on-Tyne, under the presidency of Mr. Charles Umney, F.I.C., F.C.S., in the early part of the present week. The occasion derived additional interest from this city having been the site of the first tentative meeting held in 1863. Mr. Henry Deane, Clapham, who then presided, set forth the advantages hoped for from the meetings of the pharmaceutical conference, speaking in very plain terms of ignorance, of intentional adulterations and substitutions, of recklessness in dispensing, of mystifications of formulæ, quack medicines, underselling, and other evils which should vanish as an honest love of truth, order, and precision took their place. The growth of the Conference was slow during the early years of its existence; but its usefulness in time became more fully recognised, and at present it numbers over 2000 members; and although the meetings have a very substantial supply of scientific papers, they are rendered attractive also by numerous social gatherings and excursions. This year the proceedings opened with a reception and conversazione at the College of Science on Sept. 9th, and on the following day Mr. Umney delivered his presidential address. After a brief retrospect of the work of previous years, and a graceful allusion to Newcastle as "our native heath," he passed at once to his theme, one of the articles of association agreed to in 1863—viz., "That one object of the Association should be to maintain uncompromisingly the principle of purity of medicine." In the course of his remarks upon this subject, he took occasion to refer to many questions of great interest to pharmacists—e.g., the fusion of the rival Pharmacopœias of London, Edinburgh, and Dublin into a national Pharmacopœia, the influence of the Sale of Food and Drugs Act, the relations between the Excise and the trade in medicines, and the more recent encouragement of original work by the establishment of the research laboratory by the Pharmaceutical Society. Mr. Umney's remarks upon the labour of compiling a pharmacopœia were full of sympathetic good sense. "There is, perhaps, no work upon which an expert has to use his judgment with so much tact and skill, so that he may keep both in touch and tune with the medical profession, the pharmacist, the drug merchant, and manufacturer, as when he is called upon to edit a national pharmacopœia." The recent prosecutions connected with sal volatile found ready recognition in the following words: "Is it not also desirable that pharmacists should co-operate with the Medical Council in their desire to make the British Pharmacopœia preparations legal for sale, and those of old pharmacopœias obsolete and illegal? In my opinion it is most desirable." The depressing influence upon the manufacturing pharmacy of this country hitherto exerted by the Excise regulations, and the various concessions which have recently been made, were dealt with in some detail. "Alcohol free of duty for medicinal purposes, or some facility to work with pure alcohol under supervision, is a most serious and urgent necessity. We are surely all desirous that we may not continue mere purveyors of potent remedies, but that we may be producers also, with a complete knowledge of the products we handle, whether as dispensers or traders." The concluding remarks upon the commercial value of science were of necessity brief, although they were sufficiently to the purpose. Mr. Umney evidently felt that science should be followed for its own sake rather than for any immediate prospect of reward. It might well be argued that, although the commercial results of applied botanical and chemical knowledge are great, they not uncommonly affect some clever financier, leaving the labourer the satisfaction inseparable from his work.

The "Year-book of Pharmacy," which is edited by Mr. Louis Siebold, F.I.C., F.C.S., will contain full details of the various papers read at this meeting, together with notes of the discussions.

The meeting of the British Pharmaceutical Conference is to be held next year in Leeds.

GORLESTON COTTAGE HOSPITAL.—The Gorleston Cottage Hospital, which has been in course of erection since May last, was opened on the 24th ult. by Sir H. Tyler, M.P.

Digitized by Google

HOSPITAL ATHLETICS.

THE past year has continued to show that increased amount of enthusiasm which has of recent years been a marked feature in nearly all branches of hospital athletics. There is, however, great room yet for improvement all round, and we would like to see students taking a greater interest in this part of their hospital world. A large number of them not only take no active part in athletics, but are too indifferent to interest themselves even in the prowess of their respective hospitals. Granted that in London men are placed somewhat at a disadvantage as regards athletics, still there is no excuse why they should give them up entirely and lapse into a state of listless apathy. Perhaps some shrink from athletics because in a few instances there are very evident examples of over-indulgence by some of their fellow-students, to the detriment of medical work; and teachers even have been known to condemn athletics *in toto* for the same reason; but surely such deductions are illogical. Of athletics, as of all other good things, one can have too much. Happily, however, we have only to glance at the lists of the various presidents and vice-presidents of our United Hospitals Athletic Club to see what a great interest is taken by the foremost men of our profession in this important branch of student life.

Fresh air and exercise are two very important ingredients of every practitioner's prescription for convalescent patients, but students are not compelled to cram up the minute details of these "drugs" for examination purposes; therefore they are neglected or almost wholly laid aside for the time being, and their value is only appreciated in after-life. Surely it is not making too much of a small matter to impress upon every medical student, freshman or otherwise, the necessity of keeping the body supplied with good health, as well as the mind with knowledge.

The United Hospitals Athletic Club showed still further development of activity this year by inaugurating during the summer a series of contests with their brother students at Edinburgh. These contests cannot fail to inspire greater enthusiasm amongst the adherents of both schools, and we confidently look forward to a growing interest in them year by year, and trust that the movement will spread amongst the other athletic clubs. It speaks volumes for the energy of our athletes that not only should such contests be made possible, but that the first contest should pass off so successfully and without a hitch. This meeting was held in Powderhall Grounds, Edinburgh, last July, in the presence of an enthusiastic and impartial gathering. No less than six of the ten events were most closely contested, two of them being dead heats. The United Hospitals were victorious by 7 points to 3:—100 yards: G. S. S. Marshall (U.H.) and R. A. Taylor (E.U.), dead heat. Putting the weight: W. G. West (U.H.) Long jump: R. G. Hogarth (U.H.). Half-mile: W. Kent Hughes (U.H.). 120 yards hurdles: S. Kent (U.H.). Hammer throwing: T. M. Donovan (E.U.). Mile: D. S. Duncan (E.U.). High jump: B. C. Green (U.H.) and F. Fitzgerald (E.U.), dead heat. 440 yards: W. Kent Hughes (U.H.). Three miles: A. Quennell. The Edinburgh students were most untiring in their efforts to make the trip as enjoyable as possible, and everything passed off in the happiest possible manner.

Though the Inter-hospital Athletic competition was threatened to be robbed of a great part of its interest on account of the certainty that was felt that the winners of last year would again prove victorious, yet the majority of the events were very keenly contested, and some excellent finishes were witnessed by the numerous spectators. The attendance has quite doubled during the last two years, and this has been in great measure due to the improvement in the music provided, and the executive of the sports must be assured that any efforts in a similar direction will be attended with success. The medals and cups were distributed by Mrs. Treves, and the President at the conclusion of the sports expressed his great interest in the day's proceedings and his hearty sympathy with all branches of athletics. St. Bartholomew's won with exactly the same number of events as last year—eight firsts, two seconds, and one third; they have now won the shield six times; Guy's and St. Thomas's each five times; King's and St. George's each three times, and London once. The records now stand as follows:—100 yds.: B. B. Connolly (Guy's), 10½ sec. 220 yds.: L. Stokes (Guy's), F. Little (St. Geo.), G. S. S. Marshall (Middlesex), 22½ sec. 440 yds.: T. A. Guinness (King's), 51½ sec. 880 yds.: W. Kent Hughes (St. Bart.'s), 2 min. 2½ sec. One mile: H. P. Ward (King's), 4 min. 36½ sec. Three miles: A. Quennell (St. Bart.'s), 15 min. 52 sec. 120 hurdles: J. G. Gravely (Guy's), 16⅔ sec. Putting weight: W. G. West (St. Bart.'s), 38 ft. 3 in. High jump: A. E. Nuttall (St. Bart.'s), 5 ft. 7½ in. Long jump: R. G. Hogarth (St. Bart.'s), 21 ft. 2½ in. Throwing hammer: C. T. Dent (St. George's), 90 ft. 4 in.

The Rugby Football Cup again fell to St. Thomas's Hospital, who were regarded as certain to win, as they had improved upon their team of last year, which carried all before them. Winners of first round: Middlesex, St. Bartholomew's, St. George's, Guy's, St. Thomas's, London (byes). Winners of second round: St. Thomas's, Guy's, London, and Middlesex (a draw). Winners of third round: St. Thomas's, Middlesex. Winner of fourth round: St. Thomas's. St. Thomas's team: A. S. Gedge (back); E. E. Bromet, E. W. Senior, and N. P. Toller (three-quarter backs); P. Northcote and R. W. Ord (half-backs); J. H. Dewhirst, T. A. M. Forde, P. C. Gabbett, F. W. Goodhue, J. R. Harper, W. Jackson, T. W. Lambert, W. F. Milton, C. C. Moxon (forwards). The cup has been won by Guy's four times, by St. George's and St. Thomas's each three times, by St. Bartholomew's twice, and by London and Middlesex each once.

The cricket club did not perhaps show quite so much energy as last summer, for in several instances there were difficulties in getting a team together for united hospital matches; however, they acquitted themselves very fairly on the whole; the inter-hospital ties were remarkable for the early overthrow of Guy's and St. Bartholomew's, both of whom have fought it out in the final for several years past. London and St. Thomas's met in the last round this year to compete for possession of the cup, and the latter beat their opponents rather easily, P. Northcote batting very brilliantly for them, and making a "record" for the ties by scoring 201. Winners of first round: Charing-cross, St. Mary's, St. Thomas's, Guy's, London, and University College. Winners of second round: Charing-cross, St. Thomas's, and London. Winners of third round: London and St. Thomas's (a bye). Winner of fourth round: St. Thomas's. The most prominent players in the cup ties were Messrs. Wright (Charing-cross), Poynton (St. Mary's), Isaacs and Northcote (St. Thomas's), Simpson, Kyffin, and Webb (London). The cup has been held three times by Guy's, twice by King's, and once by St. Thomas's.

In the Association Football Cup ties Guy's had again to give way, and this time to their old antagonists St. Bartholomew's, who have striven against them in the final every year since the foundation of the club in 1884 with one exception. The final tie was the most interesting of the hospital competitions, and though St. Bartholomew's won by four goals, the game was very even, and for a long time the issue was uncertain. Winners of first round: Charing-cross and Westminster, Guy's, St. Bartholomew's, St. Thomas's, Middlesex, St. Mary's and London (byes). Winners of second round: Guy's, St. Mary's, St. Bartholomew's, and St. Thomas's. Winners of third round: Guy's, St. Bartholomew's. Winner of fourth round: St. Bartholomew's. The Cup has been won four times by Guy's, and once by St. Bartholomew's. St. Bartholomew's team: J. A. Coulby, goal; E. Henry and F. E. Fernie, backs; F. Lewaine, J. Cropper, and J. G. Faber, half-backs; R. G. Hogarth and F. J. Dixon, left; A. E. Carruthers, centre; A. W. Lemarchand and N. O. Wilson, right forwards.

The Rowing Club, although it has shown more signs of life, yet has not been able to increase the number of competitors for the Inter-hospital Cup. The ties were again won by St. Thomas's, who met St. George's in the final, and won rather easily in the end, though for the first part of the course the crews were very close together. All the eight rowing in the final were Cambridge University men. Winner of first tie: St. George's, beating Guy's and Middlesex. Winner of second tie: St. Thomas's, beating St. Bartholomew's. Winner of final: St. Thomas's. St. Thomas's crew: G. C. Richardson (bow), T. W. Lambert (2), H. T. Davis (3), T. Haydon (stroke), and P. C. Phillips (cox). In the second fours, Middlesex representatives beat those of St. Thomas's and St. George's

Digitized by Google

by four lengths. Winners of Cup: 1885, London; 1886-7, Middlesex; 1888-9, St. Thomas's.

The Cross Country Challenge Cup was won by St. Thomas's, the only other hospitals represented being St. Bartholomew's and St. Mary's. Winners: 1887, St. Bartholomew's; 1888-9, St. Thomas's.

The Lawn Tennis Cup was won by St. George's Hospital, who now hold it for the second year in succession.

The Shooting Cup did not evoke much interest, as only two hospitals entered—St. Thomas's and St. Bartholomew's. The former retained their possession of the Cup, winning by 7 points.

It is interesting to note the remarkable all-round success of St. Thomas's, who, it will have been seen, carried off the Rugby Football, the Cricket, the Rowing, the Cross-country, and the Shooting Cups.

We may add that the Medical Staff Corps Cricket Club have had a very successful season this summer. They have only suffered one defeat, and have scored a large number of wins. Surgeon Trask, Corporal Forsyth, and Sergeant Lumney have been the principal contributors to their success.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Congress on Forensic Medicine: Arsenic Poisoning; Instinctive Criminals; the Selection of Experts.

THREE more subjects were discussed by the Congress on Forensic Medicine which merit special attention—namely, Arsenic Poisoning, Instinctive Criminals, and the Selection of Experts for Medico-legal Questions. On the first question a report was presented by Dr. P. Brouardel and M. G. Pouchet. This report was based in the main on the great arsenic poisoning cases of Hyères and of Havre. The result of these observations, which in these two cases were made with great care, is, that whether the case is very acute and followed by death in a few hours, or, on the contrary, very slow and lasting for several weeks, the symptoms are almost identical. In the slower cases there are no new symptoms, but each symptom may be studied in detail. Unfortunately, in the latter case the doctor does not always perceive the link which connects the various stages. Thus, at Hyères the medical men first believed there was an epidemic of gastric fever, then an epidemic of influenza and spasmodic cough; then they thought it was an epidemic that recalled acrodynia; and it was not till symptoms of paralysis appeared that all these conjectures were set aside, and the analysis of the wine showed that it was a case of wholesale but accidental arsenic poisoning. Dr. Vidal of Hyères gave to the Academy of Medicine the following chronological record. On Feb. 8th, gastric trouble, diarrhœa; March 4th, cutaneous eruptions suggesting measles, spasmodic coughing, running from the eyes and nose as in influenza; March 31st, pains in the lower limbs, cutaneous hyperæsthesia; and, a few days later, paralysis. At Havre there were exactly the same symptoms, coming in the same order, but following each other more rapidly. The vomiting is characteristic, and different from other forms of poisoning. It comes frequently, suddenly, eight or nine times a day at Hyères, but causes only slight abdominal pain and leaves no sense of burning or of acute suffering. Constipation is as frequent as diarrhœa, and there is sometimes some blood with the motions. Having described the cutaneous eruptions, the troubles of sensibility, and the final paralysis, Dr. Brouardel remarked that death often ensued from cardiac complications. This was the case with both M. and Mme. D—— at Havre. This was also noticed in the case of Mme. M——, who died suddenly at the hospital, six weeks after she had ceased taking arsenic. The quantity of poison taken may be insufficient to cause death in a few days after its absorption. There may even be time enough for the elimination of the poison; but the anatomical modifications which have taken place in the hepatic and renal cellules, in the muscular fibres, remain after the arsenic has gone, and death results. The process, may be compared to that of the toxic effects of alcoheol when death from sclerosis of the liver or the kidneys takes place long after the patient has given up drinking. When symptoms suggest the possibility of arsenic poisoning, the doctor is often in a very embarrassing position, and it is best to secure more positive evidence than that arising from the suspicious character of the disease. He cannot easily take possession of soiled linen without awakening attention. On the other hand, it is quite usual, in medical practice, to ask for a specimen of urine, and this can be done without attracting much attention. Yet even in this the medical man must see to it himself, or else perhaps the water would be changed, and thus he would be entirely thrown off the scent. Dr. Brouardel quoted the important experience of Dr. Gaillard concerning a young girl suffering from eczema, who had been overdosed with Fowler's liquid. Forty days after she had ceased taking the drug, traces of arsenic were found in the urine. On the other hand, Dragendorff has demonstrated that arsenic can be detected in the urine a few moments after it has been taken. Thus a medical man can, by an easy analysis, protect himself against the very unpleasant consequences that would ensue from a mistake committed in so grave a matter. Also arsenic is to be found in the hair, of which, under some pretext, it might be possible to secure a sample. This was done at Havre, and one hundred grammes of Mme. D——'s hair were found to contain one milligramme of arsenic. Finally, if the patient should die, the presence of arsenic can be detected in a very positive manner in the spongy tissue of the bones. The substitution of arsenic for phosphorus in the bone tissue has been thoroughly demonstrated by M. Pouchet. Whether the arsenic is swallowed or injected, the result is the same, and is all the more marked when small and continued doses have been administered. With dogs and rabbits all traces of arsenic tested with the Marsh test entirely disappeared from the viscera in three weeks, but could be seen in the bones ten weeks after the last dose of arsenic had been given. The localisation of arsenic is less accentuated; the drug is more rapidly eliminated when given in such large quantities as to produce at once the symptoms of poisoning. M. Dubouchet related his experience, and completely confirmed all that had been said. He consequently insisted on the very great utility of analysing the bones of those who were suspected of dying from the effects of arsenic.

On the last morning Dr. Garnier read a most interesting and thrilling paper on his experience in his investigations with regard to the most atrocious crime committed by Joseph Lepage. The cynicism of this youthful murderer was most remarkable. When he had passed a sleepless night he indignantly protested that it was the want of exercise and not remorse which had prevented him from sleeping. Lepage longed for the day to appear before the Assizes Court. He gloried in the publicity and in the horror his self-glorification for the accomplishment of crime would create. He displayed consistently and throughout the most complete absence of moral sense. The awful cynicism of his remarks and his boastfulness impressed the judges, as they had impressed Dr. Garnier, with a doubt as to whether they were dealing with a person really responsible for his deeds. The law at present strikes criminals who are incapable of understanding their own moral culpability. On the other hand, the moral sense of society would revolt against the idea of mixing with the insane criminals suspected of being insane. This is all the more objectionable, as every day efforts are made to reduce the restrictive measures taken in asylums. Also as an asylum is a hospital, criminals, when cured, might claim to be released. He therefore demanded that special asylums for criminals should be created. This brought the Congress round again to the point at which the discussion on the simulation of disease had ceased. One delegate remarked how completely the character of a youth at the age of puberty sometimes changed. He took to tobacco, to absinthe, and fell into evil ways. Was this due to moral decadence or to physical change? Dr. Motet dwelt on the difficulties of treating those who were very gentle in their manner, and related the case of a man who entered the house of a poor workman. He pretended to be a police agent, and insisted on examining all the premises. He found a young child whom he declared was suffering from a dangerous, infectious malady, and compelled the frightened mother to pay him five francs to remove her. He then took the child to his own room, violated her, and turned her out into the street. This man did not attempt to escape the police, and was

Digitized by Google

not conscious of having done anything wrong. Dr. Motet described another case of a man released six times from the asylum, and who six times committed acts of violence. He claimed that special asylums existed in other countries, and should also be instituted in France. Dr. Vleminckx wanted to treat instinctive criminals with very strict repressive measures, but Dr. Garnier again inquired whether a man totally devoid of moral sense should be treated as a moral criminal. A delegate here protested that this would lead us to admit that, with a few exceptions, there are no criminals. All criminals are not instinctive criminals, but a great proportion might be described as such. He thought that all criminals should be sent to prison, and not to an asylum. M. Schmy said that, while refusing to admit the irresponsibility of all criminals, he doubted whether the actual methods were good. Lepage has a brother. The two brothers were brought up together under exactly the same influences; one is a thoroughly honest, hardworking fellow; the other is the most repulsive of criminals. Was there not some physical defect to account for this otherwise inexplicable moral difference? The speaker advocated the improvement and extension of the system of reformatories. M. Ortholou, a member of the Parisian bar and a magistrate, protested that we must not only punish where punishment can moralise; we must punish when evil has been done, and not punish only when punishment may do good. We must punish first and moralise afterwards, if possible. When convicting prisoners, it had never occurred to him to inquire if the criminal would understand the moral significance of the sentence. If we are in the presence of persons who are bad, let us punish first; if good results, all the better; but in any case we must punish. This very characteristic speech rather amused the budding disciples of Prof. Lombroso. Dr. Lacassague doubted whether Lepage was really ill. He described him as a "foul flower of Paris." Such characters could not be found in the country. This "fonfaron du crime" was of town growth; and, for his part, he was willing to assist in the process of natural selection produced by alcoholism, tuberculosis, &c., and sign with both hands the execution warrant of such a monster. If a criminal, when in prison, developed genuine signs of madness, then let him be sent to a madhouse. It would be complicated to have an asylum for the insane and another for the criminals supposed to be insane. He could not see who could decide to which of these asylums each case should be sent. Dr. Semal advocated prison asylums for instinctive criminals. In ordinary asylums the doctor would not impose prison rules; he would release the patient when cured without inquiring whether he was a criminal. Our asylums were now decked with flowers and cheered with the songs of birds. There were long walks and a semblance of freedom. A separate place was evidently needed for the violent. Are not certain persons criminals? For instance, epilepsy is sometimes associated with a splendid intelligence, but never with kindness of heart. An epileptic patient may be a genius; he will never be a philanthropist. The epileptic patient may therefore be gradually converted into a criminal. He may engender a sentiment of hatred, and under the influence of the malady may kill, not the first comer, but the person he hates. This tendency will not be suppressed in an asylum; his field of action only is restrained. The access is so sudden that even in an asylum a crime may be committed. Such a person must be specially watched, and the doctor should only have a patient before him. Crime in illness is the result of an accident. The persons who are really culpable are those who are round the patient and who fail to foresee the danger. We must not wait till the crime is committed. The Commission of the Belgian Academy of Medicine had reported in favour of the creation of a special central asylum for these sort of cases, and he thought this was a step in the right direction. Dr. Lacassague maintained that in asylums there was actually a well-established system of classification, and that criminals who were really ill were treated accordingly. Thus, for instance, at the celebrated trial of the anarchists at Lyons, when Prince Krapotkine was condemned to five years' imprisonment, the speaker was consulted, and one of the anarchists was allowed special treatment. Dr. Motet, in answer, alluded to the practice in England, which he considered superior to that of France. Dr. Garnier finally replied that there were persons who are sometimes in prison, sometimes in an asylum, and this proves that they are an intermediary type; mad, sane, sometimes a bit of both, and for these a prison asylum was necessary. The President now summed up the discussion by declaring that all evidently agreed that a special asylum should be created; that the Congress thought the present state of affairs in France was defective, but could not quite decide as to what particular class of persons should be admitted to the asylum prison.

The last afternoon of the Congress proved a field day for the lawyers. The report to be discussed had been drawn up by M. Adolphe Guillot, Judge of Instruction to the Tribunal of the Seine, and M. Demange, Advocate at the Court of Appeal, and also Judge of Instruction. The names of these two lawyers are associated with some of the most celebrated trials held of late years. The question they submitted in a joint report to the Congress related to the appointment of experts in such a manner as to best protect the interests of society and of the accused. During the Universal Exhibition of 1878 this matter had been considerably discussed. On Aug. 12th, 13th, and 14th, 1878, an International Congress was held on the subject at the Tuilleries. The President of the Congress, the Hon. Dr. Devergie, in a paper on experts, commenced with the following words:—"According to certain newspapers there is a question of giving to the accused, during the course of legal investigations, certain rights which they do not now possess, notably that of demanding the appointment of counter experts." These rumours, thus treated somewhat scornfully, were well founded, for three months after the Congress, the Minister of Justice, M. Le Royer, inspired doubtless by the debates of the Congress, brought forward in the name of the Government a Bill for the complete reform of the method of criminal investigation. This Bill states: "The question of investigations by experts gives rise to many complaints. With the actual system errors once committed are almost always irreparable. The defence is only acquainted with the result of the investigation made by experts a long time after it is terminated. The objects examined have either disappeared or have greatly altered. There is no means, therefore, of control, and yet too many precautions cannot be taken, for in serious crimes this investigation of the experts is often the principal evidence produced in the accusation." The above, the text of the preamble to the Government Bill, sets forth clearly what became the subject of debate at the Congress. Should the accused himself select an expert to carry out the investigation as against the expert appointed by the prosecution? This has been proposed by M. Goblet in his Parliamentary Report of Nov. 15th, 1881, and M. Bovier-Lapierre's of Jan. 20th, 1887. The whole tendency of modern reform—and this was especially noticeable in the Cahiers des États-Généraux of 1789—has been to strengthen the defence. Nevertheless, this proposed reform with regard to experts is not yet carried, though it has been discussed for some ten years. The reporters to the Congress inquired whether the proposed innovation would work. Would a medical man, eminent in science, like to find himself called the expert for the defence? The magistrate selects his experts among the most distinguished men of science, and it is an honour to be an expert. But the criminal, for his defence, might select the most discredited practitioner he could find, someone who would not scruple to employ any stratagem to obtain an acquittal. Should the law limit the right of choice, and compel the criminal to appoint only persons of high reputation? This would cause invidious distinction, and in a great measure destroy the very principle the reform seeks to establish. Yet, again, if the criminal has the free choice of an expert, this will expose the expert appointed by the magistrate for the prosecution to personal contact with individuals of bad repute. The reporters seem to think that a list of experts should be drawn up by scientific bodies, and the prosecution and the defence should alike select from this same list. Then another difficulty arises. If the expert for the defence is to be paid by the defence, he may receive a great deal more than the expert employed by the magistrate. This will open the door to accusations of partiality. To meet this difficulty, the Parliamentary Commission, in its report on the subject, proposes that the experts should receive the same sum each, and be paid by the State. This would be a first step towards gratuitous justice, and it is advocated on the ground that the law should be as anxious to save the innocent as to condemn the guilty. Again, should both experts have the same rights and facilities of investigation? The reporters thought that, however the experts were appointed, they would always act

Digitized by Google

according to their conscience, and, while not seeking to accuse, would not try to defend, but devote their energies solely to ascertaining the truth. The real advantage would be the control—the lessening of the individual responsibility. The experts should be colleagues, and not adversaries; and should mutually seek to render the task more easy. The advocate for the defence might, perhaps, be admitted at the post-mortem investigations. It has been said that the pupils at a clinique were the body guard of the patient. Perhaps, if there was a clinique of forensic medicine, the presence of students would be the most powerful guarantee of the thoroughness and the impartiality of the investigation. Based on these principles, the report concluded with no less than nine resolutions.

The report having been read, the discussion commenced. M. Vleminckx said that in Belgium the law did not sanction the presence of a counter expert. He urged that if experts for the defence were allowed, they certainly should not be paid more than those engaged for the prosecution. M. Chaudet, a barrister, had often heard it said that experts were always in league with the public prosecutor to prove the prisoner guilty. From outward appearance it would seem that this was the case, but the public only judged from the trials that actually take place. They forget or ignore the number of prosecutions that would have been instituted but for the fact that experts, having been consulted, reported unfavourably. Dr. Lacassagne thought that the presence at the Congress of M. Demange showed the bench recognised the necessity of reform. In large towns there was but little difficulty in securing the help of experts, but in rural districts the case was very different. Young medical men, in order to gain a reputation, sought to be involved in some legal cases; it served as an advertisement; but by the time they had acquired some experience in forensic medicine their private practice increased, and then they avoided the law courts as far as possible. In a town the best man is generally appointed; a second expert could only play an inferior part. Even now, when there is but one expert, the lawyer very often consults a second expert, and is thus able to put his finger on the weak point. Sometimes a counter opinion is produced at a trial which tends to degrade the professor and does not help to get nearer to the truth. Formerly, when an affair was very difficult or serious, the expert used to ask for an assistant, but a ministerial decree had put an end to such aids. Dr. Brouardel remarked that, right or wrong, there was at present a decided current of opinion in favour of rival experts, and urged that the Congress had better utilise, in the interests of justice, a current it could not resist. The best examinations, especially in cases of assault, were those done at once; and the second expert, the expert for the defence, would be appointed too late to be present at this first examination. Again, with regard to chemical examinations—in whose laboratory should they be carried out, in that of the defence or the prosecution? Evidently not in both, and there were but few places where a neutral laboratory could be found for both experts to work in it at one and the same moment. Then, in course of time, one practitioner would acquire a reputation as an expert for the defence and another for the prosecution. In small towns and rural districts there was already too much personal rivalry and antagonism between the local practitioners, and this might lead to outbreaks of a scandalous description before the law courts. Consequently, when the local experts did not agree, it would be necessary to have a court of appeal. M. Moreau thought that on whatever side the medical man might be retained, he would do equally well his duty. It would be better that the judge should at once appoint two experts, but give the defendant the right to object to one or the other of them, and if a good reason was given the judge might appoint someone else. The same oath should be administered to both experts, and they should both be paid by the State. Dr. Vibert thought experts should be specialists. If in the matter of health specialists were consulted, surely we should do the same for the cause of justice. Forensic medicine was not a good profession; still, some doctors followed it steadily for years, and measures should be taken to prevent the dismissal of such men solely to please the caprice of a new magistrate. Dr. Da Silva, the Spanish delegate, protested that the Congress should not only consider the difference between town and rural districts, but the difference between the different nations. If by appointing two experts the Congress meant that the experts were to take sides, this was altogether against the spirit and dignity of science. A medical man could have only one object in view, that of ascertaining the truth, and would degrade the profession if he allowed himself to be employed for any other purpose. It was not his mission to attack or to defend; he could only be called upon to give impartial testimony. M. Demange replied that the current in favour of contradictory debate was too strong, and this was accepted, with melancholy good humour, by Dr. Brouardel. For the dignity of science there should be no contradictions made before the tribunal. Though both sides were to choose experts, these could only be selected from a carefully-prepared list. Both experts would be equal; they would not issue rival, but, on the contrary, joint reports. If they did not agree, then they would have to ask for the creation of a superior or higher court. Dr. Da Silva did not like the idea of the defendant being able to refuse a specialist. The defendant could not refuse the magistrate or the prosecutor. Also in some special case, there might be only one man available, capable of acting as an expert. The defendant, by refusing to accept this expert, would throw the case into incompetent hands. M. Guillot thought the plurality of experts a good thing; he scorned all ideas of economy, and had himself sometimes employed two and three experts.

The Congress now proceeded to vote on the resolution. The first, to the following effect, was carried unanimously: "To guarantee the interests of society and of the accused in all medico-legal investigations, at least two experts shall be employed." The next sentence, "These shall be appointed by the judge," was carried by a small majority, for a large minority voted in favour of each side appointing its own expert. A resolution giving the defendant the right to object to one of the experts was lost. The difficulty of drawing up lists of experts was further discussed. Dr. Brouardel stated that, though 500 medical men came out every year from the Paris Faculty of Medicine, he did not think thirty were fit to act as experts. The facilities of communication reduced this difficulty, as experts could be brought from a distance. The Congress then voted: "That experts, except in special cases requiring special knowledge, shall be chosen from lists drawn up by the public powers and the scientific bodies selected for that purpose. The system of the plurality of experts imposed the constitution, at the seat of the Faculties of Medicine, of a Supreme Council of Forensic Medicine, which shall act as a high and final court of appeal." With respect to this latter resolution, it was pointed out that a similar institution had worked very well in Germany. At first there had been many cases referred to this court, but in a short time it was found to act as an excellent check against careless investigation, and now the cases sent up on appeal were not at all numerous. The Congress then carried the following resolutions without any further discussion and without any opposition:—"The Judge of Instruction should be present at the post-mortem &c., except in special cases, so as to supply to experts such information as may guide their researches. The lawyer retained for the defence may also be present, so as to point out to the experts the objections the defence may raise. A class comprising the general principles of legal medicine should complete in the law schools the study of criminal law. It would be well, so as to facilitate the study of legal medicine, if exception were made to the principle of professional secrecy in so far as to admit the presence of students at post-mortem examinations, unless this for special reasons is vetoed by the judge. It would be well to create in schools of forensic medicine or in law courts archives and collections of all articles which served as evidence, and which the magistrates and experts thought useful for the teaching of forensic medicine."

Having thus successfully disposed of the resolutions, Dr. Brouardel rose and thanked the foreign members of the Congress for their attendance and for the zeal they had displayed. If the Congress was not numerous, this was due to many other causes than that of indifference to the questions at issue. Their subject was very restricted; the number of persons capable of participating in the discussion was very limited. Nevertheless, though the Congress was not numerously attended, it had done its work in a remarkably business-like manner. The questions had been thrashed out with great perseverance, and the speeches were well to the point. No one had indulged in utopian flights; all had proved themselves intensely practical. When the volume which the full report of the proceedings would make was read, it would not fail to produce a good impression.

Digitized by Google

He therefore congratulated the Congress on its work, and declared its labours were concluded.

The members quietly left the large amphitheatre, and soon formed groups in the court, where, for the most part, they discussed which of the rival holiday resorts would be the best resting-place after the fatigues of so many Congresses.

Paris, Sept. 3rd.

THE BRITISH ASSOCIATION.

THE fifty-ninth annual meeting of the British Association commenced at Newcastle-on-Tyne on Wednesday, the 11th inst., twenty-six years having elapsed since the last meeting of the Association in that town. Sir Frederick Bramwell, F.R.S., the retiring President, having, in a few appropriate words, introduced his successor in the chair—Professor Flower, F.R.S.,—the latter proceeded to deliver his address. As chief of the Natural History Museum in London, the new President's speech was, as might be expected, directed to a subject upon which he is so great an authority—namely, the practical organisation of museums, and in an effective and lucid manner and at considerable length, he explained the true principles upon which collections of natural history objects should be arranged so as to bring them most easily and quickly under the eyes of the visitor, or within the scope of the scientific investigator. Overcrowding in museums was to be deprecated at all costs. The President urged that the first consideration in establishing a museum, large or small, ought to be that it should have some definite object or purpose to fulfil, and that the means should be forthcoming to maintain the museum in a suitable manner to carry out that purpose. Every specimen exhibited should be good of its kind, and all available skill and care should be spent upon its preservation, so as to render it capable of teaching the lesson it was intended to convey. At the conclusion of the address a hearty vote of thanks was accorded to Professor Flower. The President expressed his acknowledgment of the vote, and announced that the number of tickets issued for the present meeting of the Association amounted to 2228.

PRIZES AT THE MEDICAL SCHOOLS.

THE following is a list of the Prizes, &c., awarded at the various medical schools, for the Sessions 1888–89:—

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—Lawrence Scholarship and Gold Medal: Bedford Pierce. Brackenbury Medical Scholarship: J. A. Hayward. Brackenbury Surgical Scholarship: C. H. Roberts. Senior Scholarship in Anatomy, Physiology, and Chemistry: A. G. Gave. Open Scholarships in Science, Senior: N. Soden; Junior, J. W. Pickering. Preliminary Scientific Exhibition: R. E. Scholefield. Kirkes Scholarship and Gold Medal: W. F. Oakeshott. Bentley Prize (Medical): F. W. Andrewes. Bentley Prize (Surgical): E. A. Edelston. Hichens Prize: W. B. Jones. Wix Prize: A. B. Boyd. Harvey Prize: H. N. Armstead, A. S. Blackwell (equal); 3, H. O. Davy; 4, W. B. Jones; 5, N. Wilson; 6, C. E. Wheeler; 7, A. N. Weir; 8, H. J. Walton. Skynner Prize: B. Pierce, W. G. Willoughby (equal). Practical Anatomy, Junior: Treasurer's Prize—1, W. N. Soden; 2, H. S. Elworthy; 3, C. R. H. Crawford; 4, A. H. Buck; 5, J. O. March; 6, A. F. Stevens; 7, B. Ley; 8, A. D. Allen; 9, E. S. Humphry; 10, R. C. T. Stevens. Practical Anatomy, Senior: Foster Prize—1, N. Wilson; 2, W. B. Jones; 3, H. W. Armstead; 4, O. Holst; 5, A. N. Weir; 6, H. O. Davies, W. E. Miles (equal); 8, J. C. Baker; 9, F. Lewarne, B. G. Seton (equal). Shuter Scholarship: J. Attlee. Junior Scholarships: A. S. Blackwell; 2, H. W. Armstead; 3, A. A. Weir.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—Session 1888–89.—£125 Entrance Scholarship: Mr. A. R. Rendle. £65 Entrance Scholarship: Mr. G. E. Hale. £50 Entrance Scholarship: Mr. E. G. G. Little. The Acland Clinical Prize in Medicine: Mr. W. K. Fyffe. Pollock Prize in Physiology: Mr. N. Elrington. The Henry Charles Johnson Prize in Anatomy: Mr. H. A. Hinge. Assistant Demonstrator of Anatomy: Mr. H. A. Hinge.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—Llewellyn Scholarship, certificate and £25, F. H. A. Taylor; Golding Scholarship, certificate and £15, C. H. J. Lockyer; Governors' Clinical Gold Medal, F. H. A. Taylor; the Pereira Prize, certificates and £5, T. E. Constant and A. H. Smith (equal). Senior Anatomy: Prize, A. W. W. Hoffman; certificates, W. M. Palmer, F. B. Rockstro, and H. W. J. Cook. Junior Anatomy: Prize, N. R. J. Rainier; certificates, J. W. Willson and E. Clowes. Senior Physiology: Prize, A. W. W. Hoffman; certificate (*proxime accessit*), H. W. J. Cook; certificates, D. C. P. Taylor, W. M. Palmer (equal), H. Gillett, J. P. Oliver, G. T. Bishop, and F. B. Rockstro. Junior Physiology: Prize, G. H. Hooper; certificates, W. May, E. R. Bull, J. W. Willson, K. Schelling, and W. R. Barrett. Practical Physiology: Prize, A. W. W. Hoffman; certificates, C. H. J. Lockyer, and W. M. Palmer, H. W. J. Cook, and J. Busfield (equal). Chemistry: Prize, G. H. Hooper; certificates, R. F. S. Wallace, H. H. Woods, A. W. Denny J. W. Willson, E. J. Rowbotham, P. C. Spark, and W. R. Barrett. Practical Chemistry: Prize, J. H. Day; certificates, W. M. Palmer, D. C. P. Taylor, and M. B. Foster, S. C. Bright (equal), A. V. Knowles, and S. B. Axford, A. W. W. Hoffman, J. P. Oliver, and C. C. Jeffery (equal). Osteology: Prize, W. R. Barrett. Medicine: Prize, H. S. Baker; certificates, H. J. F. Badcock and Charles Gibbs. Junior Practical Medicine: Prize, J. Busfield; certificate (special), G. F. Dickinson; certificate, H. S. Baker. Senior Practical Medicine: Prize, G. F. Dickinson; certificate (*proxime accessit*), Charles Gibbs. Surgery: Prize, G. F. Dickinson; certificates, A. Carling and E. L. Rowse (equal). Minor Surgery: Prize, S. F. Cheesman; certificates, J. W. Willson, E. J. Eedle, and J. H. Day. Therapeutics: Prize, F. H. A. Taylor; certificates, M. Dobbs and T. E. Constant. Materia Medica: Prize, A. W. W. Hoffman; certificate (special), C. H. J. Lockyer; certificates, G. T. Bishop, T. H. Lawrie, and H. D. Senior. Midwifery: Prize, J. F. Colyer; certificate, G. F. Dickinson. Forensic Medicine: Prize, F. H. A. Taylor; certificate, G. F. Dickinson. Pathology: Prize, G. F. Dickinson; certificate, J. Busfield. Dental Surgery: First prize, certificate, and £6 6*s*., J. A. Mallett; second prize, certificate, and £4 4*s*., E. Preedy; certificates, A. R. Colyer and W. May (equal).

GUY'S HOSPITAL MEDICAL SCHOOL.—The Treasurer's Gold Medal for Clinical Medicine, Ernest Henry Starling (Bombay). The Treasurer's Gold Medal for Clinical Surgery, Robert Devereux Mothersole (Colchester), and Ernest Henry Starling (Bombay), *proxime accessit*. Gurney Hoare Prize of £25 for Clinical Study, George Herbert Pennell (Exeter). Beaney Prize of 30 guineas for Pathology, Ernest Henry Starling (Bombay). Mackenzie Bacon Prize of £15 for Nervous Diseases, Arthur Henry Williams (Hayton, Yorks). Golding Bird Medal, and Prize of £20 for Methods of Diagnosis, Robert Devereux Mothersole (Colchester). Michael Harris Prize of £10 for Anatomy, John Henry Bryant (Ilminster). Fourth-year students: Alfred Parkin (Hightown, Yorkshire), first prize, £25; Robert Devereux Mothersole (Colchester), second prize, £10. Third-year students: Frederick William Hall (Sydney, New South Wales), £25. Second-year students: John Henry Bryant (Ilminster), £11 13*s*. 4*d*.; Bertram Whewell Hogarth (Morecambe), £11 13*s*. 4*d*.; Arthur Stanley Wohlmann (Hertford), £11 13*s*. 4*d*., equal; William Gusterson Rogers (Kimberley, South Africa), certificate; Charles Edward Salter (Barnes Common), certificate. First-year students; Alfred Theodore Rake (Fordingbridge), first prize, £50; Thomas Holmes (Lancaster), second prize, £25; Edward Thomas Ernest Hamilton (East Dulwich), certificate; Tom Robinson Taylor (Methley, near Leeds), certificate; Charles Caldwell Elliott (Wynberg, Cape Colony), certificate; Harry Bacon Wilkinson (Southport), certificate; Arthur Mantel Daldy (Romford), certificate. Open Scholarship in Arts of 125 guineas, John Beresford Leathes (Rochester). Open Scholarship in Science of 125 guineas, William John Johnson (Shefford, Beds).

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Broderip Scholarships, for the best examination at the bed-side and in the post-mortem room:—First, H. A. Daniel; second, J. K. Clarke; *proxime accessit*, E. E. Norton. Governors' Prize: E. C. Long. Hetley Prize: E. C. Long. Exhibition in Anatomy (first year): A. E. Bodington. Lyell Medal: E. C. Long. Murray Medal and Scholarship: E. C. Long. Medicine: C. H. Fazan. Surgery: E. C. Long. Practical Medicine and Therapeutics: Evan Jones. Practical Surgery: E. C. Long. Practical Midwifery: W. H. Fosbery. Anatomy: T. Carwardine. Physiology: H. W. Gibson. Chemistry: F. E. Rock. Dissections: H. W. Gibson. Pathological Anatomy: H. W. Kendall. Midwifery: F. A. Alderson. Forensic Medicine: H. B. Shepherd. Materia Medica: E. W. Gregor. Practical Chemistry: F. E. Rock. Practical Physiology: E. H. Williams. Entrance Scholarships: First, H. Bankes Price; second, A. E. Bodington; exhibition, A. Jones.

LONDON HOSPITAL MEDICAL COLLEGE.—Entrance Science Scholarships: £60 scholarship, F. J. Wollacott; £40 scholarship, R. G. Kirton. Buxton Scholarships: £30 scholarship, W. S. H. Sequiera; £20 scholarship, A. Russell. Clinical Medicine: £20 scholarship, given jointly by the House Committee and the Medical Council, G. F. Oldham; honorary certificate, F. R. Riley. Clinical Surgery: £20 scholarship, given jointly by the House Committee and the Medical Council, J. A. Offord; honorary certificates, W. C. Aylward and E. J. Hicks. Clinical Obstetrics: £20 scholarship, given jointly by the House Committee and the Medical Council, W. C. Aylward and F. J. W. Porter (equal); honorary certificate, F. R. Riley. Duckworth Nelson Prize: Prize, £10, E. J. Hicks; honorary certificates, G. F. Oldham and W. C. Aylward. Letheby Prize: £30 prize for proficiency in Chemistry, E. E. Blomfield; honorary certificate, S. H. Rayne. Anatomy, Physiology, and Chemistry: £25 scholarship given by the Medical Council, E. E. Blomfield; honorary certificate, J. Mulvany. Anatomy and Physiology: £20 scholarship, given by the Medical Council, H. L. Barnard; honorary certificate, W. S. H. Sequiera. Dressers' Prizes for Zeal, Efficiency, and Knowledge of Minor Surgery, given by the House Committee: £15 prizes, E. E. Blomfield and ——; £10 prizes, J. Mulvany and A. T. Hirsch; £5 prizes, —— and ——. Practical Anatomy Prizes: £5 prize, J. McNeal; £5 prize, J. Mulvany; £5 prize, J. R. Preston; £5 prize, H. L. Rutter.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Entrance Scholarship in Natural Science of 75 guineas, C. T. Parsons; 75 guineas, J. S. Collier; 50 guineas, F. J. Poynton; 50 guineas, J. E. B. Wells. University Entrance Scholarship of 50 guineas, G. E. C. Pritchard, B.A. Oxon.; £50, E. H. Colbeck, B.A. Cantab., G. Wilkinson, B.A. Cantab., W. W. Simmons, B.A. Cantab. Classical Scholarship of value of £50, W. Charrington Wood. Mathematical Scholarship of value of £50, T. T. Brunyate, Christchurch, Oxford. Summer Session, 1888: Second year: Midwifery—L. Rogers, prize; G. M. Winter, certificate of honour. Medical Jurisprudence—G. M. Winter, prize; H. L. Hatch, L. E. Parkhurst, and L. Rogers (equal), certificates of honour. First year: Materia Medica—G. G. Clarke, prize; R. B. Manning, D. Maddock, F. J. Worth, A. V. Crossing, and E. A. Nathan, T. E. Smurthwaite (equal), certificates of honour. Botany—R. Gilmour, prize; C. A. Lane, certificate of honour. Chemistry—E. W. Simmons, prize; R. B. Manning, and F. H. Daynes, E. A. Nathan, H. W. Clarke, T. E. Smurthwaite (equal), certificates of honour. Histology—H. G. Lane-Pryce and J. O. Symes, prizes; E. A. Nathan, certificate of honour. Winter Session, 1888-9: Third year: Medicine—Prize not awarded; L. Rogers and G. Wilkinson (equal), certificates of honour. Surgery—L. Rogers, prize; G. Wilkinson, certificate of honour. Practical Surgery—L. Rogers, prize; G. Wilkinson, certificate of honour. Pathology—L. Rogers, prize; G. Wilkinson, certificate of honour. Third and fourth years: Clinical Medicine—C. G. Mack, prize; A. B.

Digitized by Google

Batley and C. H. Powers, certificates of honour. Clinical Surgery—J. J. Knox, prize; A. H. Bindloss (*proxime accessit*), and C. G. Mack, G. M. Winter (equal), certificates of honour. Prize in Ophthalmology of £10 10s.—J. Griffith, prize; ditto (prize divided)—H. A. Kidd and R. B. Ferguson (equal). Pathology Scholarships—A. C. Rendle and L. Rogers, prizes. Second year: Anatomy—J. R. Evans, prize; J. O. Symes and F. J. Worth, certificates of honour. Physiology—C. A. Lane, prize; E. A. Nathan, R. B. Manning, and J. O. Symes, certificates of honour. First year: Anatomy—C. T. Parsons, prize; J. S. Collier, certificate of honour. Physiology—C. T. Parsons, prize; J. S. Collier, certificate of honour. Chemistry—H. Roberts, prize. Special prizes, 1888: Students of first year, for general proficiency in Anatomy, Physiology, Materia Medica, and Chemistry—R. B. Manning. Students of second year, for general proficiency in Anatomy, Physiology, Midwifery, and Medical Jurisprudence—G. M. Winter. Students of third year, for general proficiency in Medicine, Surgery, Pathology, and Operative Surgery—R. H. Cole. Prosectors—N. E. Norway and F. J. Worth. Special prize for best Drawings and Note-book in the Physiology Classes—Mander Smyth. [1] Obtained number of marks equal to the prize winner.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Summer Session 1888.—First-year students: J. H. Fisher, college prize, £15, and certificate of honour; C. S. Wallace, college prize, £10, and certificate of honour; W. B. Winston, certificate of honour; W. Watkins-Pitchford, certificate of honour; W. P. Purvis, certificate of honour; C. S. Jaffé, certificate of honour; P. C. Gabbett, certificate of honour; W. G. Sutcliffe, certificate of honour; W. L. Wainwright, certificate of honour. Second-year students: A. King, college prize, £15, and certificate of honour; D. F. Shearer and E. T. Whitehead (equal), college prize, £10, and certificates of honour. Third-year students: A. Wentworth Jones, college prize, £15, and certificate of honour; C. C. Heywood, college prize, £10, and certificate of honour; A. C. Lankester, certificate of honour.—Winter Session, 1888-89:—Entrance Science Scholarships: E. M. Hainworth, scholarship, 125 guineas, and certificate of honour; E. Smith, scholarship, £60, and certificate of honour. First-year students: E. Smith, the William Tite Scholarship, £27 10s., and certificate of honour; W. G. Sutcliffe, college prize, £20, and certificate of honour; C. Planck, college prize, £10, and certificate of honour; L. V. Tebbs, certificate of honour; H. M. Moore, certificate of honour; J. W. Hewett, certificate of honour; G. J. Arnold, certificate of honour; K. B. J. Vickers, certificate of honour; W. Redpath, certificate of honour; C. L. B. Stares, certificate of honour; C. W. Grant-Wilson, certificate of honour; E. M. Hainworth, certificate of honour; E. Miskin, certificate of honour. Second-year students: J. H. Fisher, the Musgrove Scholarship, £38 10s., and certificate of honour; C. S. Wallace, college prize, £20, and certificate of honour; W. B. Winston, college prize, £10, and certificate of honour; A. Banks, certificate of honour; W. Potter, certificate of honour; J. G. Turner, certificate of honour; C. Latter, certificate of honour; W. A. Bowring, certificate of honour; A. M. Campbell, certificate of honour; W. Watkins-Pitchford, certificate of honour; W. E. Drake and W. P. Purvis (equal), certificates of honour; W. L. Wainwright, certificate of honour; C. S. Jaffé, certificate of honour; T. W. Hicks, certificate of honour. Third-year students: J. J. Perkins, college prize, £20, and certificate of honour; W. H. Millar, college prize, £15, and certificate of honour; A. King, college prize, £10, and certificate of honour; E. T. Whitehead, certificate of honour; C. P. Lovell, second tenure of the Peacock Scholarship. Surgery and Surgical Anatomy: A. C. Lankester, the Cheselden medal; A. F. Stabb, T. W. Lambert, and H. W. Nix, special mention and certificates of honour. Practical Medicine: S. G. Toller, the Mead medal; A. W. Musson, T. A. Dukes, and A. Wentworth Jones, special mention and certificates of honour. For general proficiency and good conduct: A. F. Stabb, the Treasurer's gold medal.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Honours List (Summer Session).—Materia Medica: W. H. A. Tebbs, prize; H. Wolseley-Lewis, H. A. Stonham, T. W. Bailey, W. B. Winckworth, certificate. Practical Chemistry: W. H. A. Tebbs, prize; T. W. Bailey, H. A. Stonham, W. B. Winckworth, H. H. Mills and E. C. Drake (equal), G. Norman, J. A. L. Campbell and H. W. Lewis (equal), certificate. Histology: A. S. G. Bell, prize; T. W. Bailey, certificate. Pathology: E. J. Pritchard and P. M. Yearsley (equal), prize. Midwifery: P. M. Yearsley, prize; E. J. Pritchard, certificate. Forensic Medicine and Toxicology: P. M. Yearsley, prize. Honours List.—Entrance Scholarships (Winter), H. Witham, £80; (Summer) E. Spencer, £100; E. Nowell, £40; H. M. Dowler, £40. Treasurers' Prize for first winter subjects, value 10 guineas, W. H. A. Tebbs. President's Prize for second-year subjects, value 20 guineas, A. S. G. Bell, and H. W. Lewis, J. B. Byles, *prox. accesserunt*. Bird Prize and Medal, value £15, P. M. Yearsley. Chadwick Prize, value 20 guineas, not awarded. Clinical Medicine Prize, value £5, Ll. Lewis. Clinical Surgery Prize, value £5, not awarded. Class Prizes and Certificates.—Anatomy—Senior Class: J. B. Byles, H. W. Lewis, A. S. G. Bell, H. A. Stonham; Junior Class: W. H. A. Tebbs. Physiology—Senior Class: H. A. Stonham, A. S. G. Bell, J. B. Byles and H. W. Lewis (equal); Junior Class: W. H. A. Tebbs. Histology—Senior Class: A. S. G. Bell, H. W. Lewis, J. B. Byles, H. A. Stonham. Chemistry—Junior Class: W. H. A. Tebbs, prize. Medicine—Senior Class: A. S. G. Bell, prize. Surgery—Senior Class: P. M. Yearsley, prize.

UNIVERSITY COLLEGE, LONDON.—Atkinson Morley Surgical Scholarship: W. W. H. Tate. Atchison Scholarship: T. L. Pennell. Sharpey Physiological Scholarship: W. D. Halliburton, M.D., B.Sc. Fellowes Clinical Medallists, 1888, Summer Session: M. G. Foster, W. Gordon, W. W. H. Tate, and H. H. Horden; Medallists, 1889, Winter Session: T. L. Pennell, P. R. Dodwell, Douglas Drew, and E. R. C. Earle. Liston Gold Medallist: T. L. Pennell. Alexander Bruce Gold Medallists: L. E. Hill and T. L. Pennell. Tuke Silver and Bronze Medallists: L. E. Hill and T. L. Pennell. Cluff Memorial Prize: A. Griffith. Erichsen Prize: W. S. Routledge.

BRISTOL MEDICAL SCHOOL.—Chemistry: Prize, V. Moxey; certificates, T. M. Carter, H. B. Wilson, E. A. Duffield, C. W. J. Brasher, and J. Freeman. Practical Chemistry: Prize, H. B. Wilson; certificates, T. M. Carter, V. Moxey, and J. Freeman. Botany: Prize, H. B. Wilson. Practical Physiology and Histology: Prize, A. W. Peake; certificates, E. G. C. F. Atchley, H. B. Wilson, T. M. Carter, and J. H. Parsons. Materia Medica and Therapeutics: Prize, A. W. Peake; certificates, T. M. Carter, J. Freeman, and V. Moxey. Obstetric Medicine: Prize, F. H. Edgeworth; certificate, B. G. M. Baskett. Practical Surgery: Prize, H. S. Jackson; certificates, F. E. Scrase, S. H. Lucy, and B. G. M. Baskett. Pathology and Morbid Anatomy: Prize, E. G. Hall; certificates, T. C. Grey, H. F. Ormerod, F. H. Edgeworth, C. A. Griffiths, and G. F. Bergin. Practical Pathology and Morbid Anatomy: Prize, T. C. Grey; certificates, C. A. Griffiths, H. L. Ormerod, F. H. Edgeworth, E. G. Hall, and G. F. Bergin. Medical Jurisprudence: Prize, T. C. Grey; certificates, C. A. Griffiths, H. L. Ormerod, J. S. Griffiths, and R. H. Norgate. Junior Classes of Anatomy and Physiology: Prize, W. H. Ligertwood. Junior Class of Anatomy: certificates, W. R. Hadwen, J. C. Smyth, F. C. Fosbery, M. F. Staniland, and R. H. Chilton. Junior Class of Physiology: certificates, W. R. Hadwen and J. C. Smyth. Senior Class of Anatomy: Prize, J. H. Parsons; certificates, A. W. Peake, T. M. Carter, C. W. J. Brasher, V. Moxey, and P. H. M. Star (equal). Senior Class of Physiology: Prize, A. W. Peake; certificates, J. H. Parsons, T. M. Carter, V. Moxey, C. W. J. Brasher, and J. Freeman. Class of Practical Anatomy: Prize, T. M. Carter; Prosectors' certificates, C. W. J. Brasher, T. M. Carter, and A. W. Peake. Class of Medicine: Prize, T. C. Grey; certificates, C. M. Vernon and C. Wintle. Class of Surgery: Prize, H. S. Jackson; certificates, T. C. Grey and C. Wintle. Class of Hygiene: Prize, H. L. Ormerod; certificates, E. G. Hall and R. H. Norgate.

BRISTOL ROYAL INFIRMARY.—Entrance Scholarship (of the value of 35 guineas): W. H. Ligertwood. Entrance Scholarship (of the value of 10 guineas): E. A. Duffield. Suple Medical Prize (a gold medal value 5 guineas, and 7 guineas in money) for fourth-year Students: H. L. Ormerod. Suple Medical Extra Prize of 7 guineas: E. G. Hall. Suple Medical Extra Prize of 3 guineas: C. M. Vernon. Suple Surgical Prize (a gold medal value 5 guineas and 7 guineas in money), for third-year Students: C. Wintle. Clark Prize (of the value of 15 guineas), for that Student of the Infirmary who has most distinguished himself in the class examinations open to Students in their third year at the Medical School: H. S. Jackson. Tibbits' Memorial Prize (of the value of 9 guineas), for proficiency in Practical Surgery: F. Lace. Crosby Leonard Prize (of the value of 7 guineas), for proficiency in Clinical Surgery: F. H. Edgeworth. Pathological Prizes (each of the value of 3 guineas): F. Dymoke, G. H. Skinner, C. B. Gratte, F. Lace, J. H. Fardon, and H. J. Thomas.

BRISTOL GENERAL HOSPITAL.—Lady Haberfield Entrance Scholarship (of the value of 30 guineas): C. W. J. Brasher. Clarke Scholarship (of the value of £15), for proficiency in Surgery, open to Students of the third year: B. G. M. Baskett. Sanders Scholarship (of the value of £22 10s.), for proficiency in Medicine, Surgery, and Obstetric Medicine, open to Students of the fourth year: G. F. Bergin, C. A. Griffiths (equal). Martyn Memorial Pathological Scholarships (each of the value of £10), for proficiency in Pathology and Morbid Anatomy: April, R. F. E. Austin; October, G. F. Bergin, C. A. Griffiths (equal). Committee Gold Medal (awarded to the Student of the fourth year who has most distinguished himself during his career at the Hospital and the Medical School): T. C. Grey. Committee Silver Medal (awarded to the next most distinguished Student of the fourth year): G. F. Bergin.

LEEDS SCHOOL OF MEDICINE.—Anatomy: Prize, C. A. Dixon; certificate, J. L. Iredale. Anatomy (Junior): Prize, J. M. Nicol; certificate, T. L. James. Physiology: Prize, C. A. Dixon; certificates, J. L. Iredale and J. G. Rowell. Physiology (Junior): Prize, J. M. Nicol; certificates, E. W. S. Hughes and T. L. James. Practical Physiology: Prize, C. A. Dixon; certificate, C. Waddington. Chemistry: Prize, J. M. Nicol; certificate, A. W. Scott. Practical Chemistry: Prize, J. G. Rowell; certificate, H. Keighley. Materia Medica: Prizes, H. Walker, J. G. Rowell; certificates, C. Forsyth, C. Benson, C. A. Dixon, and A. Ellison. Midwifery: Prize, J. J. Mitchell; certificate, C. Benson. Gynæcology: Prize, J. G. McCandlish; certificate, R. Wilkinson. Surgery: Prize, Jas. Stalker; certificate, C. Benson. Medicine: Prize, J. J. Mitchell; certificate, A. E. Sellers. Thorp Prizes in Forensic Medicine: First, T. P. Braim; second, C. Forsyth and J. J. Mitchell. Thorp Prize in Hygiene: J. Stalker. Hardwick Prize: H. E. Hick.

UNIVERSITY COLLEGE, LIVERPOOL.—Holt Tutorial Scholars: G. W. Chaster and J. Gould. Lyon Jones Scholar (Senior): V. B. Bennett. Lyon Jones Scholar (Junior): B. Stahlknecht. Derby Exhibitioner: J. Gould. Torr Gold Medallist: J. Evans. Junior Gold Medallist: F. J. Woods.

CARMICHAEL SCHOOL OF MEDICINE.—Carmichael Scholarship: V. K. Cooke. Mayne Scholarship: E. Kennedy. Medical Jurisprudence: E. Du Cane. Midwifery: R. Creighton. Physiology: J. Dowling. Botany: W. Allen. Practical Chemistry: Ethel Joel. Practical Histology: J. H. Farmer. Anatomy (first year): W. Black, F. Rogers, W. H. Anderson; (second year): J. Dowling, J. H. Farmer, R. T. Moynan. Chemistry: G. Griffith, W. Black, and E. Hamilton.

LONDON SCHOOL OF DENTAL SURGERY.—Saunders Scholar, A. W. W. Hoffman; Ashs' Prize, K. Schelling. Certificates, J. H. Day, A. W. W. Hoffman. Mechanical Dentistry: First prize, Mr. J. H. Day; second prize, A. W. W. Hoffman; certificates, C. F. Badcock, J. Dunlop, V. Knowles. Metallurgy: First prize, A. W. W. Hoffman; second prize, S. C. Bright; certificates, J. A. Mallet, J. H. Day. Prize in Operative Dental Surgery: First prize, J. B. Hordern; second prize, G. G. Spray; certificates, F. Burton, J. Dunlop. Dental Anatomy: First prize, A. W. W. Hoffman; second prize, E. J. Preedy; certificates, W. May, J. H. Day, K. Schelling. Dental Surgery: First prize, A. W. W. Hoffman; second prize, E. J. Preedy; certificates, E. R. Bull, T. Coysh, L. C. Tomlyn, J. H. Day. Students' Society prize, F. A. Harsant.

NATIONAL DENTAL HOSPITAL AND COLLEGE.—Rymer Medal: J. N. Dunlop. Dental Anatomy: R. S. Faro, prize, and J. N. Dunlop, prize (equal); E. A. H. Field, certificate. Dental Mechanics: S. Keele, prize; J. N. Dunlop, certificate; A. Prager, certificate. Metallurgy: A. Moore, prize; F. E. Cutts, certificate. Dental Surgery: J. N. Dunlop, prize; W. Rushton, certificate, and F. T. Haycroft, certificate. Operative Dental Surgery: Prize and certificate not awarded. Dental Materia Medica: Prize not awarded; F. T. Haycroft, certificate; S. Keele, certificate. Elements of Histology: S. Keele, certificate. Mechanical Work: Prize not awarded. Student's Society: R. S. Faro, prize.

SCHOOL OF MEDICINE, EDINBURGH.—Class of Chemistry, Surgeons' Hall: Class Medals, (1) John Lister Armitage, Thirfield, Yorkshire; (2) Adam Dryden, Edinburgh; (3) Charles Allan Brough, London, and Alexander Elder, Edinburgh. Class of Practical Chemistry: Class medals, Charles Allen Brough, London; George Henry Peake, Madagascar; George Stephenson Shirt, India. Class of Medical Jurisprudence: Junior Division, (1) M. A. Bamby, Bangalore, India; Senior Division, O. R. Lewis, London, and Douglas Stanley (equal). For Best Notes of Dissection in Class: (1) Douglas Stanley. Class of Public

Digitized by Google

Health: Junior Division, (1) William Polson; Senior Division, P. C. Smith, Durham. For Best Essay on Abattoirs: (1) A. K. Melville. Class of Clinical Surgery, Royal Infirmary: Senior, (1) W. J. H. Cumming; Juniors, (1) F. J. L. Lorimer, and (2) F. J. Bonnalie (equal). Class of Practice of Physic, 27, Nicolson-square: Senior, (1) C. N. C. Wimberley, Inverness; Junior, (1) R. D. Rudolph, Nova Scotia. Class of Materia Medica and Therapeutics, Minto House: Silver medal, Joseph Eugène, Horace Gentil, Mauritius. Class of Practical Materia Medica, including Practical Pharmacy: Silver medal, Robert Scott, M.A., Melbourne. Class of Chemistry: Medal, T. A. Coward, Carlisle; second prize, William L. Dickson, Edinburgh; third prize, George Edward Gabites, New Zealand. Class of Chemistry, 41, Chambers-street: Silver medal, H. W. Bolam, Leith. Class of Practical Chemistry: Medal, George W. Pollard, Taunton. Class of Anatomy, Minto House: Senior prizeman, E. R. Harriott, Jamaica; Junior prizeman, Adam Dryden, Edinburgh. Class of Practical Anatomy: Senior Gold Medallist, Robert J. Ashton, Calcutta; Silver Medallist, R. M. Horne, Slamannan; Second-year men, Silver Medallist, J. M'Clymont, Kirkcudbrightshire; First-year men, Division A., Silver medal, D. H. Beegling, New South Wales; Division B., Silver medal, Adam Dryden, Edinburgh. Class of Practice of Physic, Surgeons' Hall: Medals, (1) A. J. Prentice, Lanark; (2) W. Polson, Sutherlandshire. Dental Students: Medal, F. J. Bonnalie, Chester. Class of Principles and Practice of Medicine, Park-place: Senior Division, (1) William Everett, Kettering; Junior Division, (1) Thos. J. Burton, Edinburgh. Class of Materia Medica and Therapeutics, Surgeons' Hall: Medallist, Edward Hughes, North Wales. Special Examination in Therapeutics: Prizeman, John Cuthbertson Walker, Dumbartonshire. For Assistance in the Work of the Class: Special prize, Charles Edward Lester, New South Wales.

EDINBURGH.—Class of Systematic Surgery, 27, Nicolson-square.—Senior Division: Prize, Rhys Davies, South Wales. Junior Division: (1) Arthur E. Shepherd, Adelaide, Australia. Practical Class.—Senior Division: Prize, David Westwood, Perthshire. Junior Division: Prize, Arthur E. Shepherd, Adelaide. Class of Systematic Surgery, Surgeons' Hall.—Senior Division: (1) Charles G. MacLeod, Fife. Junior Division: (1) F. J. Bonnalie, Chester. Class of General Pathology.—Silver medals: William Wood, Yorkshire, and Fred Graham, Monmouth (equal). Bronze medal: Frank T. Foster, New Zealand. Class of Practical Pathology.—Bronze medal: John Maclaren, Edinburgh. Class of Theoretical Botany, Minto House.—Medallist: J. Owens. Class of Practical Botany.—Medallist: J. Kerr. Class of Anatomy, Surgeons' Hall.—Gold Medallists: J. B. Davies, Lampeter, and G. V. Lockett, Jamaica (equal). Systematic Anatomy.—Seniors: Medallist, Henry Taafe, Londonderry. Juniors: Medallist, C. A. Brough, London. Practical Anatomy.—Juniors: Medallists, (1) W. Fitzgerald, New Zealand, and (2) C. A. Brough, London. Practical Anatomy (second year).—Medallists: Gabriel Barbeau, Mauritius, and L. G. Fink, Calcutta (equal). Practical Anatomy.—Seniors: Medallists, (1) J. C. Williams, Rhyl, and (2) W. B. Macleod, Edinburgh. Class of General Pathology, Nicolson-square.—Certificate and first prize, W. F. Robertson, Roxburghshire; certificate and second prize, M. A. Bamby, Bangalore. Class of Diseases of the Tropics and Climatology, Park-place.—First prize, E. C. Foston, Penang; second prize, George A. Wolfendall, Tutbury. Class of Systematic Surgery.—Seniors: First-class honours, (1) E. G. Pilgrim, Barbadoes; second-class honours, John Maclaren, Edinburgh. Juniors: First-class honours, (1) Charles Martin, Middlesborough; second-class honours, (1) Arthur T. Kember, S. India. Class of Midwifery and Diseases of Women.—Prizes, (1) William Paterson, Ayrshire; (2) James Currie, M.A., Kelso; (3) G. Trafforde Tuke, Edinburgh. Class of Institutes of Medicine, Surgeons' Hall.—Medals and Certificates of Merit, (1) Frederic J. Hare, Darlington; (2) Henry J. Glover, Goalhouse-on-Fleet; (3) Charles D. Sutherland, Aberdeenshire. Class of Practical Physiology.—Medal and certificate, Alexander Gibson Clark, Forfarshire. Class of Surgery, Chambers-street.—Prizes, (1) E. Forsyth, Berwickshire; (2) James Spencer, Glasgow. Class of Systematic Surgery, Minto House.—Senior Division: Prize, W. M. Parham, Bath; Junior Division: Prize, F. C. F. Foster, New Zealand. Class of Chemistry, Marshall-street.—Silver Medallist, James W. Horne, Stirlingshire. Class of Practical Chemistry.—First-class honours, (1) B. Harbottle; (2) W. H. Coupland; (3) W. Harper.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Condition of the Hoo Rural District, by Mr. SPEAR.—This district comprises a tongue of land that stretches into the estuary formed by the confluence of the rivers Thames and Medway; one half is marsh, but there is also an elevated range of London clay, capped here and there by gravel, the local industry being, apart from some brickmaking, almost purely agricultural. It is evidently a district lying under suspicion, for it had already been visited, on behalf of the Local Government Board, by Dr. Airy in 1881, and by the late Dr. De Chaumont, in connexion with the cholera survey in 1885. The story told by Mr. Spear is one that is altogether uninteresting apart from administrative considerations, for it is that of a district long since shown to have but few of the sanitary requisites of a healthy population, and one in which little progress has been made, notwithstanding that the defects and needs of the several localities composing it have been more than once pointed out. As regards disease, it is stated that diphtheria has become notably more prevalent and more fatal during recent years, and the village of Hoo is referred to as one of the places that has suffered most. One cause of this state of affairs is explained to be the complete absence of any proper organisation in the sanitary machinery of the district, there being no community of action between the medical officer of health and the inspector of nuisances, and it is especially urged on the sanitary authority that they should give heed to that portion of the Order of the Local Government Board relating to the duties of the inspector of nuisances, and which distinctly contemplates that this officer should to a large extent work under the direct superintendence and supervision of the health officer of the district.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5429 births and 2972 deaths were registered during the week ending Sept. 7th. The annual rate of mortality in these towns, which had been 19·2, 17·2, and 16·9 per 1000 in the preceding three weeks, further declined last week to 16·2, and was lower than the rate in any previous week of this year. During the first ten weeks of the current quarter the death-rate in these towns averaged 19·0 per 1000, and was 1·4 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 13·2 in Leicester, 13·9 in Bristol, 14·0 in London, and 14·5 in Wolverhampton. The rates in the other towns ranged upwards to 20·7 in Manchester, 25·4 in Plymouth, 26·0 in Preston, and 26·9 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases, which had been 811, 636, and 543 in the preceding three weeks, further declined last week to 512; they included 255 from diarrhœa, 63 from "fever" (principally enteric), 59 from scarlet fever, 58 from whooping-cough, 40 from measles, 37 from diphtheria, and not one from small-pox. These zymotic diseases caused the lowest death-rates in Derby and Birkenhead, and the highest in Sunderland, Preston, and Plymouth. The greatest mortality from diarrhœa occurred in Salford, Sunderland, Leicester, Blackburn, Newcastle-upon-Tyne, Hull, and Preston; from "fever" in Bradford, Norwich, Plymouth, Bolton, Preston, and Huddersfield; from scarlet fever in Plymouth, from whooping-cough in Sunderland, and from measles in Newcastle-upon-Tyne, Sunderland, and Preston. The deaths from diphtheria included 30 in London, 2 in Liverpool, and 2 in Preston. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1021, against numbers increasing in the preceding ten weeks from 559 to 966; 121 cases were admitted to these hospitals during the week, against 98 and 136 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 162, 115, and 148 in the preceding weeks, were last week 142, and were 25 below the corrected average. The causes of 57, or 1·8 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Bradford, Portsmouth, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Sheffield, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·8 and 18·1 per 1000 in the preceding two weeks, declined to 16·5 in the week ending Sept. 7th; this rate exceeded by only 0·3 the low rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 11·1 and 11·6 in Perth and Paisley to 15·0 in Aberdeen and 21·2 in Glasgow. The 423 deaths in the eight towns showed a decline of 26 from the number in the previous week, and included 24 which were referred to diarrhœa, 18 to whooping-cough, 10 to "fever" (typhus, enteric, or ill-defined), 9 to diphtheria, 3 to measles, 2 to scarlet fever, and not one to small-pox; in all, 66 deaths resulted from these principal zymotic diseases, against 91 and 74 in the preceding two weeks. These 66

Digitized by Google

deaths were equal to an annual rate of 2·6 per 1000, which was 0·2 below the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 48 and 31 in the preceding two weeks, further declined last week to 24, of which 13 occurred in Glasgow, 3 in Edinburgh, and 3 in Aberdeen. The 18 deaths from whooping-cough were within one of the number in the previous week, and included 10 in Glasgow, 4 in Dundee, and 2 in Leith. The 10 deaths referred to "fever" showed an increase upon the numbers in recent weeks; 6 were returned in Glasgow and 2 in Aberdeen. The fatal cases of diphtheria also exceeded the numbers in recent weeks, and included 3 in Glasgow, 3 in Leith, and 2 in Edinburgh. The deaths from measles and scarlet fever, on the other hand, showed a further decline from recent weekly numbers. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 48 and 55 in the previous two weeks, were last week 54, and 21 below the number returned in the corresponding week of last year. The causes of 39, or more than 9 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·4, 25·1, and 26·6 per 1000 in the preceding three weeks, declined to 18 6 in the week ending Sept. 7th. During the first ten weeks of the current quarter the death-rate in the city averaged 22·7 per 1000, the mean rate during the same period being 16·8 in London and 15·6 in Edinburgh. The 126 deaths in Dublin showed a decline of 54 from the number in the previous week; they included 11 which were referred to diarrhœa, 2 to whooping-cough, 1 to "fever," 1 to measles, and not one either to small-pox or diphtheria. Thus the deaths from these principal zymotic diseases, which had ranged in the preceding five weeks from 15 to 34, declined again last week to 15; they were equal to an annual rate of 2·2 per 1000, the rate from the same diseases being 2·1 in London and 1·4 in Edinburgh. The deaths referred to diarrhœa, which had increased in the previous five weeks from 8 to 26, declined again last week to 11. The deaths from "fever" also showed a marked decline. The deaths, both of infants and of elderly persons, showed a considerable decline from the numbers in recent weeks. Six inquest cases and 3 deaths from violence were registered; and 29, or nearly a quarter, of the deaths occurred in public institutions. The causes of 13, or more than 10 per cent., of the deaths in the city were not certified.

THE SERVICES.

THE *London Gazette* of the 6th inst. contains the official account, by Major-General Sir F. Grenfell, K.C.B., of the battle fought at Toski, and which ended in the total defeat of the Dervishes. Speaking of the services rendered by the medical staff, the Sirdar says: "When the reconnaissance developed into a general action, Surgeon-Major Hayes quickly returned to camp, arranged an increase of eighty beds on the seventy already organised, improvised a bearer column, and all wounded received first field dressings as they fell, and seriously wounded men were conveyed to hospital by stretcher parties and camels. This rapid organisation reflects great credit on Surgeon-Major Hayes, and the following officers of his department:—Surgeon Morse, S.M.O., 1st column; Surgeon Lewis, Extemporised Bearer Column; Surgeon Pinching, S.M.O., 2nd column, and I have every reason to be satisfied with all his arrangements for Egyptian wounded. In addition to the care of Egyptian wounded. Surgeon-Major Hayes had arranged for a large number of Dervish sick and wounded, and has worked night and day to alleviate their sufferings. He is a most able, active, and energetic officer."

ARMY MEDICAL STAFF.—Brigade Surgeon Caleb Sherar Wills, C.B., has been granted retired pay (dated Aug. 24th, 1889); Surgeon James Perceval Myles has been seconded for service with the Egyptian Army (dated Aug. 4th, 1889).

INDIA OFFICE.—The Queen has approved of the following admissions to the Indian Medical Service (dated March 30th, 1889):—To be Surgeons: Bengal—Fairlie Russell Ozzard, Adam Rivers Steele Anderson, John Telfer Calvert, Edgar Jennings, Theodore Mayo Stiles, and Arthur Gervase Hendly. Bombay—William Symonds Percival Ricketts, Charles Malcolm Moore, George William Jenney, and Charles Tilson Hudson.

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon Wm. Coates resigns his commission (dated Sept. 4th, 1889).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon James D'Arcy Harvey has been placed on the Retired List of his rank, at his own request; Surgeon Arthur William Egerton Brydges Barrett has been allowed to withdraw from Her Majesty's Naval Service with a gratuity.

The following gentlemen have been appointed Surgeons in Her Majesty's Fleet (dated Aug. 22nd):—George Allan, M.B.; William J. Maillard, M.B.: Percy V. Jackson; Oswald M. Jones; Nicholas C. Ridles; Alfred H. L. Cox; Erington F. S. M'Kay; and Alexander Maclean, M.B. The following appointments have also been made:—Surgeon Charles W. Hamilton to the *Wye;* Surgeon T. J. Crowley, M.D., to the *Boscawen;* Surgeon William E. Beal to the *Sultan;* Surgeon George K. Bell, to Chatham Hospital, temporarily; Fleet Surgeon Henry N. M. Sedgwick to the *Duke of Wellington*; Fleet Surgeon Henry A. Close to the *Northumberland*, vice Sedgwick; Staff Surgeon Richard J. Barry to the *Phæton;* Surgeon W. Slaughter, B.A., M.B., to the *Ajax;* and Surgeon Reginald T. A. Levinge to the *Hotspur.*

VOLUNTEER CORPS.—*Artillery:* 2nd Volunteer (Essex) Brigade, Eastern Division, Royal Artillery: Harold Gurney, Gent., to be Acting Surgeon (dated Sept. 4th, 1889).—1st Banff: Acting Surgeon F. W. Grant, M.D., to be Surgeon (dated Sept. 4th, 1889).—*Rifle:* 1st Volunteer Battalion, the Royal Warwickshire Regiment: Acting Surgeon E. L. Freer to be Surgeon (dated Sept. 4th, 1889).—3rd Volunteer Battalion, the Lancashire Fusiliers: Acting Surgeon W. E. Husband to be Surgeon (dated Sept. 4th, 1889).—1st Volunteer Battalion, the Duke of Wellington's (West Riding Regiment): Acting Surgeon J. Martin to be Surgeon (dated Sept. 4th, 1889).—1st Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment) Acting Sur- E. Vaudrey, M.B., to be Surgeon (dated Sept. 7, 1889).

Correspondence.

"Audi alteram partem."

CHLOROFORM AS AN ANÆSTHETIC.

To the Editors of THE LANCET.

SIRS,—I wish to criticise a few of Mr. Horsfall's remarks in his letter in favour of chloroform as an anæsthetic.

He says: "How rarely do we hear of a death *under* it; *from* it almost never." In the medical journals for the last ten years there are reported one hundred and twenty (if not more) cases of death under chloroform. Many of these are very imperfectly described, but in at least forty-nine cases the patients were in good general health at the time of administration, and required an anæsthetic merely for the performance of some minor operation—e.g., extraction of teeth (eleven cases of death), reduction of dislocations (nine cases), eye operations, fistulæ, and so on. In some fifty-nine cases death occurred before the commencement of the operation, and so was clearly due to the chloroform alone. In about twenty of the cases it is noted that chloroform had been successfully given on previous occasions; in one, as many as eight different times before the fatal administration. It is evident from the foregoing that chloroform is uncertain in its action; that not only do people die while *under* chloroform, but also *from* it—frequently, too, even when it is used by skilful hands. Of course, it is possible to retort that "it was not properly given," which may be correct. This will not alter the fact that these accidents prove chloroform to be a powerful agent, very difficult to administer properly—indeed, so difficult and dangerous that it is scarcely suitable for a routine anæsthetic, when a drug less powerful for evil can replace it.

Mr. Horsfall emphasises the objections to ether, without noticing the means of overcoming them. Its "nauseous flavour" and "the sense of suffocation" can be entirely done away with by the use of nitrous oxide, and its inhalation made more agreeable than even that of chloroform,

Digitized by Google

while the patient quickly becomes unconscious without the struggling so common with chloroform. I have not yet found a single patient who has once inhaled ether preceded by nitrous oxide complain of suffocation or object to take it again on the ground of its unpleasantness.

The readiness with which chloroform affects the heart, the smallness of a fatal dose, and especially the ease and suddenness with which such a dose can be inhaled almost by a couple of deep inspirations, will make its safe exhibition always a difficult task to invariably accomplish. Without having had so many years' experience, I have given chloroform successfully nearly as many times as Mr. Horsfall, and have gradually come to believe it to be a less safe anæsthetic than ether.

I am, Sirs, yours obediently,

ALEXANDER WILSON,

Administrator of Anæsthetics to the Manchester Royal Infirmary and Victoria Dental Hospital.

Sept. 3rd, 1889.

NOTIFICATION OF INFECTIOUS DISEASES.

To the Editors of THE LANCET.

SIRS,—Your leading article of August 31st on this subject, coming as it does after the passing of the obnoxious Bill, is as oil and wine to those who have taken part in opposing that measure. We appear to be worsted, but I am one of those who do not consider the game by any means played out yet. Something has been gained by our agitation in the fact that the dual system is not enforced over the whole country, and Mr. Walter McLaren, M.P., says that at his request (which was certainly most opportune) the chief clause has been altered so that the medical man has not (as intended) to state the name of the person whom he considers primarily liable, but only the name, address, and disease of the patient. Of course the effect on the householder will be the same, but we shall not be quite such *common* informers.

And now I wish to vindicate myself (and my statistics on this subject) from the attack of Professor Corfield, who, in *The Times* of August 28th, besides saying other unpleasant things, wrote as follows:—

"Mr. Biddle alludes to statistics prepared from the Registrar-General's reports, and concludes from them 'that the dual system is on the average destructive of life.' I would refer those who are anxious to ascertain the value of conclusions drawn by him from statistical tables to the controversy which took place between him and Dr. Whitelegge, the medical officer of health for Nottingham (now medical officer of health for the Western Division of Yorkshire), in the *British Medical Journal*, in March, April, and May of the present year. They will there find that Mr. Biddle argued that a reduction in the number of deaths from 1000 to 950 was equal to a reduction of from 50 to 0 if the population were equal; in other words, that 'the good effected would be the same' with a reduction of 5 per cent. of the deaths as with the abolition of the death-rate, and they will readily understand that Dr. Whitelegge did not consider such an argument worthy of a reply."

In the first place, I beg to say that I did not expect any reply from Dr. Whitelegge, since he had already expressed a resolve to write no more, and in the last letter from which Professor Corfield "quotes" I was merely availing myself of the usual right of terminating the discussion which I had begun. Secondly, I was treating of the death-rates from preventable diseases, in which zero is by no means an absurdly impossible limit. Year after year the death-rate from small-pox is *nil* in several of even the large towns, and in some does not average 0·005 per 1000 for ten years together.

But in order that your readers may judge fairly betwixt us, I will ask you to be kind enough to reproduce the passages in two of my letters from which Professor Corfield may be supposed to quote (or rather *mis*quote). The first[1] is as follows:—

"The principle of expressing the increase or decrease in the effect of any disease upon a community by the *ratio* between death-rates at given epochs, as by Dr. Whitelegge's system of percentages, is far from satisfactory, inasmuch as where the death-rate has been low slight vicissitudes produce too great an effect upon the estimate; and where, on the contrary, the death-rate has been high, a considerable change is apt to pass almost unnoticed. Thus, for instance, in the case of small-pox, it seems altogether unfair to regard a reduction in the average number of deaths in a town from 40 to 20 as no more than equivalent to a reduction from 4 to 2 or 2 to 1. It is far more just to take the *difference* between the average death-rates at two epochs, and thus obtain the actual yearly saving (or loss) of life per 1000 of the population, in the latter period as compared with the former."

The second letter[2] runs thus:—

"When Dr. Whitelegge attempts to invalidate the method adopted by me of taking the difference rather than the ratio between the death-rates of two epochs in order to estimate increase or decrease, which method I adopted because it shows the actual saving or loss of life per 1000 of the population, and when he says, 'To take another illustration, a reduction from 1000 to 950 would be equivalent to a reduction from 100 to 50 or from 50 to 0,' I beg to observe that such would not be the case, unless the populations compared were equal. But given this equality, the good effected would, so far as the evidence goes, be the same in all three instances, however different in potency might be the salutary influences brought to bear; and if the deaths in the first town went on decreasing by fifty each year until they reached zero, I should say that they did so by equal annual decrements, and, if the average population remained the same, at an equal annual rate.

"At the same time, there cannot be reduction of a death-rate which is already *nil*, nor is it fair to compare towns or groups of towns whose average death-rates did not, at the earlier of the two given epochs, afford pretty equal scope for reduction. I am ready to grant, therefore, that the ratio would serve as an estimate almost equally with the difference, if the commencing death-rates were on a par; but Dr. Whitelegge has disregarded this proviso.

"Now the two sub-groups of towns which I selected for comparison in my last letter, had (to commence with) death-rates almost identical, not only from zymotic diseases as a whole, but from these as differentiated into notifiable and non-notifiable. The advantages as regards number of towns (in the group), average population, and density were all on the side of the dual-notification group; and yet, whereas in 1871–76 the average death-rate of this group from notifiable diseases was only 2·55, as against 2·64 in the non-notification group, there was in 1881–86 a reversal of the relations, the death-rates from notifiable diseases being respectively 1·05 and 1·01."

On reviewing these passages I see no reason whatever for recantation on my part, but feel confident that recognised statisticians other than medical officers of health will agree with me that the effect produced upon a group death-rate by a reduction of 50 in the number of deaths in a particular town of that group would be precisely the same whether the previous number of deaths in that town were 1000 or only 50. In fact, it is easy to see that in either case 50 lives would be saved to the country, neither more nor less, in a population of given extent. If Dr. Whitelegge and Professor Corfield mean that it is always or even generally easier to reduce a high death-rate than a low one, I should like to know how this can be asserted with the evidence before our eyes of London and Manchester. The former, without any system of notification to control its teeming millions, has declined considerably in its death-rate, which for four years has been under 20 per 1000, and last year was only 18½; whilst the latter, with all the advantage (?) of the dual system, has become a public scandal, owing to the height at which its death-rate keeps, rarely falling below 27.

I am, Sirs, your obedient servant,

D. BIDDLE.

Kingston-on-Thames, Sept. 2nd, 1889.

To the Editors of THE LANCET.

SIRS,—Allow me to heartily thank you, on my own part and that of many others, for your able endeavours to prevent the medical profession from passing under the degrading yoke of the dual clauses of Mr. Ritchie's Bill. The profession have not been fairly dealt with in the matter of this Bill; for, to hurry it through committee of the House in the last week of the session, when the Government knew that every medical member was absent and all other opponents of the dual system also, except one, is not consonant with the principle of fair and just legislation, and such a proceeding merits the strong condemnation which

[1] Brit. Med. Jour., April 27th, 1889.

[2] Ibid., May 18th, 1889.

Digitized by Google

you have passed upon it in your leader of the 31st ult. Your arguments, and those of others, against medical notification have been very apt and able, and I am sorry that the official mind has not been more favourably impressed by their force and gravity.

In *The Times*, whose columns are now closed to discussion, there appeared on the 28th ult. a letter from Dr. Farquharson, in which he states his impression that the medical men of Kingston were not unanimous in their opposition to the dual clauses of the Kingston Improvement Bill. The fact that not one member of the profession refused to join in our opposition, except the medical officer of health of the Corporation, and that eighteen, residing within a mile and a quarter of the Town Hall, and including four other medical officers of health, most liberally subscribed to a fund to carry the opposition into both Houses of Parliament, will be sufficient, I hope, to remove that impression.

I am, Sirs, yours obediently,

Kingston-on-Thames, Sept. 3rd, 1889. T. CORBETT.

THE MAYBRICK CASE.

To the Editors of THE LANCET.

SIRS,—Though I was simply amazed at the verdict of "Guilty" after the lack of any evidence whatsoever to prove to the jury that Mrs. Maybrick administered, or attempted to administer, arsenic with a criminal intent to the deceased, my feeling of surprise was trivial compared to that experienced on reading Mr. Bond's letter in your columns today. Mr. Bond, after severely condemning the evidence of Drs. Tidy and Macnamara, insists that the deceased died from arsenic poisoning, and suggests that Mrs. Maybrick poisoned her husband with a solution of arsenic from the fly-papers she bought. The Home Secretary, however, after an exhaustive review of the evidence, a re-examination of some of the medical witnesses, and additional legal and medical advice, distinctly states that there is a reasonable doubt whether the death was caused by the administration of arsenic. This official deliverance is a complete answer to Mr. Bond's insistance that the man was killed by arsenic.

Mr. Bond, though he thinks that the fly-papers were the source of the arsenic wherewith he asserts that Mr. Maybrick was poisoned, dwells on the grave suspiciousness of the large quantities of white arsenic found in the house, adding that in several cases of poisoning this form (arsenious acid) was used. Does he mean that Mrs. Maybrick gave the deceased arsenious acid and also arsenic from the fly-papers, the latter of course in solution? If so, why was so very little arsenic found in the body? As I read the evidence, Mrs. Maybrick was accused of administering the poison in solution, *not* of administering the solid form.

Again, when was the large quantity of arsenious acid found? After death; and there was no evidence to show that Mrs. Maybrick had either bought or placed it where it was found. Thereby, I have no doubt, hangs a tale. It is a mystery for the nonce, but it was for the Crown to prove that Mrs. Maybrick procured and placed it, neither of which they attempted to do. That suspiciously large store (more than seventy grains) *might* have been deposited by some other woman or man; but, even on the hypothesis that Mrs. Maybrick was a poisoner, what purpose could this enormous quantity, placed where it could easily be found, have served her?

I entirely disagree with Mr. Bond's opinion, and am satisfied that no proof has been adduced in public of the death of the husband by arsenic poisoning.

I was present at Madeline Smith's trial in Edinburgh thirty-two years ago. In her case there was a clear motive (the removal of a lover who had threatened to stop an eligible marriage by the production of compromising letters). There was a large quantity of the poison found in the body of the deceased, and she was proved to have bought the poisonous substance. Yet an intelligent Scotch jury returned a verdict of "Not proven." *That* jury would assuredly have acquitted Mrs. Maybrick, against whom the evidence was so much weaker.

It seems to me unwarrantable, on Dr. Stevenson's evidence as to the small quantity of arsenic detected by him, especially in the absence of some well-known and characteristic symptoms of arsenic poisoning, to conclude that the deceased must have died from poisoning, and I rejoice to find that Mr. Matthews has come to the conclusion that there is reasonable doubt on the subject. I have no doubt that all concerned—judge, jury, and witnesses on both sides—have been conscientious and straightforward, but human life and liberty are too precious to be lost on mere suspicion. It was for the Crown to prove the accused guilty, which they clearly failed to do. They only proved that the circumstances were suspicious. I have strong hope that Mr. Matthews, whose conduct I cannot too highly praise, will by-and-by completely fulfil the full requirements of reasonable doubt of the alleged offence (murder) by opening the prison door. It is to be regretted we have no Medico-Legal Society which could dispassionately discuss the trial.

I am, Sirs, your obedient servant,

NORMAN KERR, M.D.,
Vice-President (permanent) of the International Congress
Aug. 31st, 1889. of Medical Jurisprudence.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the able letter of Mr. Bond in your issue of Aug. 31st, and fully agree with him in the opinions therein expressed. It is remarkable how few cases are recorded of the post-mortem appearances of poisoning by arsenic in solution, and the departure from the more usual appearances to be expected under such circumstances seems to have been largely overlooked in the Maybrick case. Of course, such points are not liable to occur to a cross-examining counsel unless they are specially suggested to him at the time, and it is quite conceivable that those who might have been expected to be alive to the point were so astounded by the statement that the symptoms observed pointed away from arsenical poisoning that they did not have the questions put to the witnesses who gave such extraordinary evidence. But it is worthy of remark in this connexion that Woodman and Tidy, in their "Handbook of Forensic Medicine and Toxicology," state that "sometimes the patient dies without any bad or severe symptoms at all." It is clear, therefore, that the absence of certain symptoms, which led Dr. Tidy to dispute the theory of arsenical poisoning in the Maybrick case, finds a parallel in other cases quoted by himself.

There is one point in the Maybrick case of which many of the commentators appear to be ignorant; that is, that all the solid arsenic found was in admixture with charcoal (not with soot or indigo, which are the substances prescribed by law for mixing with arsenic). There was a chocolate box containing a stained handkerchief and a paper packet labelled "Arsenic; poison for cats." There were two bottles containing the same cat poison mixed with water. It seems probable that whoever used the cat poison found the presence of charcoal an inconvenience, and hence tried to remove it by adding water and filtering the solution through a handkerchief. This operation would probably prove unsuccessful, and hence cause a resort to fly-papers as a source of arsenic. It is not likely that Mr. Maybrick would willingly eat a mixture of arsenic with charcoal, and he had no occasion to separate the charcoal; for, besides a box nearly full of arsenical pills, Mrs. Maybrick states that he possessed a white powder which, at his request, she added to the meat-juice. If she had done so, some would probably have remained undissolved, whereas the analyst found the poison to be wholly in solution. Mrs. Maybrick states that she added a considerable quantity of water to the meat-juice to replace some of the liquid which she accidentally spilt, which is a strange action on the part of a person not in a position to fear punishment for carelessness. On the other hand, if an infusion of fly-papers were added to the meat-juice, the presence of arsenic (wholly in solution) and the dilution observed by the analyst would both be accounted for.

Much has been made of the absence of arsenic from the stomach of the deceased and of the small quantity found in the liver. In a previous case of undoubted poisoning by arseni al fly-papers (that of Flannigan and Higgins), the same analyst, Mr. Davies, only found twice as much arsenic as he *actually extracted* from Mr. Maybrick's liver. But Mr. Davies stated in evidence that he believed in Mr. Maybrick's case he only succeeded in extracting one-half of that present, and, as a matter of fact, the portion of liver examined by Dr. Stevenson was three times as rich in arsenic as that analysed by Mr. Davies.

I am, Sirs, yours respectfully,

ALFRED H. ALLEN, F.I.C., F.C.S.,
Past President of the Society of Public Analysts, &c.
Sheffield, Sept. 3rd, 1889.

"THE USE OF ROBURITE IN MINES."

To the Editors of THE LANCET.

SIRS,—I did not see the letter of "The Writer of the Article" in time to reply last week. In closing the discussion, so far as I am concerned, I would only beg to point out that my letter was addressed to the practical point of the *use* of roburite in mining, tunnelling, quarrying, &c, and I expressly asked to have the unfortunate accident at Gathurst eliminated from consideration, as it occurred during the *manufacture* of roburite, and from an operation which should certainly not have been performed by manual labour. I regret that "The Writer of the Article" should have supposed I wished to contend that dinitro-benzol, one of the organic components of roburite, is not poisonous if absorbed into the system, although it is certainly not so injurious as the more volatile nitro-benzol, of which latter roburite contains but a trace, produced during manufacture. My whole object in writing to you was to produce reliable evidence that, when *used* under proper and simple precautions, roburite does not produce an injurious effect upon the health; also that the gaseous products of explosion (fumes) were not different in kind from those produced by most other high explosives, though less in quantity. As to the far more injurious character of the fumes produced by fired gunpowder, I need say nothing. I may conclude with the illustration that when H R.H. Princess Henry of Battenberg fired a shot of roburite at the Winnstay Colliery, Ruabon, the other day, general surprise was expressed at the small quantity of the fumes; this has been my personal experience on many occasions.

I am, Sirs, your obedient servant,

Sept. 10th, 1889. W. H. WARDELL, Major-General.

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR.

To the Editors of THE LANCET.

SIRS,—In reference to your article on the treatment of fracture of the neck of the femur, I write to say that I have had several instances—two in old people—of complete bony union after treatment with the contrary-to-authority Liston's long splint, the fracture having first been reduced and then kept well up against the splint with broad woollen cravats, or large old-fashioned handkerchiefs, round the pelvis and chest. I use a large handkerchief, with tow or wool in the middle, and folded corner-wise, for counter extension, and a plaster stirrup for the foot, and, with old people, have a thin, soft bed on the hard one.

I am, Sirs, yours truly,

Rhymney, Sept. 3rd, 1889. T. HALL REDWOOD.

"HINTS TO STUDENTS BEGINNING."

To the Editors of THE LANCET.

SIRS,—Everyone must agree with your correspondent, "Experientia docet," in advising students to see something of private practice while going through their course, but why should they be recommended to reside with a physician? He does not dispense, or work a parish appointment, or attend clubs; nor does he usually see the numerous trivial cases that are so important for a student; and, what is more, he rarely keeps books or sends out accounts. Surely it would be far better for a student to reside with a general practitioner, who could initiate him into the mysteries of all classes of practice, and into those of dispensing and book-keeping as well.—I am, Sirs, yours truly,

Woolwich, Sept. 11th. THEODORE MAXWELL.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Medicine.

THE appearance of the "Students' Number" of THE LANCET, with other indications that September is now come, warn us of the near approach of the opening of the Medical Faculty of the Liverpool University College. Liverpool has possessed a Medical School for more than half a century. It began as the Royal Institution School of Medicine, then became the Royal Infirmary School of Medicine, and has now expanded into the Medical Faculty of the Liverpool University College. It received some impetus in the year 1860 owing to a considerable increase in the number of students. But it is to Mr. Reginald Harrison that the school must always be indebted for its present position. Under his able management as Registrar and Demonstrator of Anatomy it acquired a position which it has never lost, but to which it has made considerable augmentations.

The Anatomical Rooms and Physiological Laboratory.—As anatomy and physiology are the basis of all real medical education, it has for years been recognised at this School that the practical study of Anatomy and Physiology is of primary importance. Those who remember the old dissecting-room of thirty years ago, find it very difficult to identify it now, enlarged, added to, and altered as it has been out of all recognition. Professor Mitchell Banks still occupies the chair of Anatomy, which he has now filled for many years. He is ably assisted by Mr. Thomas, F.R.C.S., and Mr. Gould; the supply of subjects is unlimited, and the facilities for acquiring a thoroughly practical knowledge of anatomy are such as could hardly be exceeded in any medical school. The Physiological Laboratory is amply furnished with microscopes and all other requirements for the teaching of Physiology, even up to the present high standard. Professor Caton and Mr. Larkin have charge of this department.

The *Chemical Laboratories* have been established in buildings recently erected for the purpose at considerable expense. Professor Campbell Brown is an analyst of repute, and students can learn Chemistry from the standard sufficient to enable them to pass the more ordinary examinations up to those for honours at the Victoria or any of the Universities. In this as in all other departments of the school care has been taken to make the teaching thoroughly practical.

Medicine and Surgery.—Professors Glynn and Rushton Parker lecture respectively upon Physic and Surgery; each has held his chair for some years past, and the classes are well attended. Provision for the practical study of both these important subjects will be found in the wards of the Royal Infirmary, where clinical lectures are regularly given.

The New Royal Infirmary.—There is every reason to hope that the winter session 1890–91 will find the professors, medical staff, residents, and students comfortably established in the newly erected and rapidly completing buildings of the Royal Infirmary, the most complete institution of the kind which has hitherto been erected. For the present, provisions for the accommodation of patients, and the clinical teaching of medicine and surgery have been made in temporary wards erected for the purpose and in the wards of the Lock Hospital. In the new infirmary there will be, in addition to every modern improvement, the most ample facilities for clinical teaching and reasonable opportunities of obtaining the various positions of clinical clerk, dresser, post-mortem clerk, house physician and house surgeon.

Other General Hospitals.—Although the close proximity of the Royal Infirmary to the School must always attract the larger number of students, some have availed themselves of the opportunities provided by the Northern and Royal Southern hospitals for the clinical study of medicine and surgery, at both of which hospitals one or more professors of the School hold office as physicians or surgeons. Both of these hospitals, being situated in convenient proximity to the Northern and Southern Docks respectively, receive annually a large number of accidents and urgent cases, affording to the students and resident surgeons almost unlimited opportunities for the study of fractures, dislocations, and other injuries. The Stanley Hospital, though more distant, is conveniently accessible by rail and tramcar, and also affords great opportunities for the clinical study of medicine and surgery.

When the new infirmary is reopened the Lock Hospital will be again ready for the reception of patients of both sexes suffering from syphilis and other venereal diseases. The male wards will be open as formerly to the students of the School for clinical study, clinical lectures being given by the surgeons every week. As might be expected in such a city as Liverpool, the number of cases of venereal disease exceeds very greatly the accommodation made for them. In addition to the eye department of the Royal Infirmary, there is the Eye and Ear Infirmary within a few minutes' walk of the School. Still nearer is the Ladies' Charity and Lying-in Hospital, the out-patient department of which provides the students with obstetric cases. The Thornton

Digitized by Google

wards of the infirmary will be an admirable field for the study of gynæcology under Dr. Wallace, the Professor of Obstetrics.

It would be impossible to give within the compass of a letter all the advantages which the Liverpool School offers to students. A collegiate residence for them is still in the future. But comfortable lodgings at most reasonable charges can be had near the College and in all parts of the city, as well as on the Cheshire side of the Mersey. Some medical practitioners receive pupils into their houses, while a limited number will be received into the infirmary and hospitals. A student can complete his medical curriculum here, or study for a year or more with great profit to himself, even should he have been at another provincial or a metropolitan school of medicine. Liverpool has had for many years the reputation of being a place for cotton-selling and money-making, for shipping and freights. It is all the more creditable to it and to the men who have nobly toiled for years amidst discouragement and difficulties, that they have effected what they have. Liverpool can now successfully compete with those ancient places where

"Learning with its eagle eye
Seeks Science in her log abode."

Death under Chloroform at Liverpool.

An inquest was recently held by the Liverpool city coroner upon the body of a boiler-scaler aged twenty-two, who went into the workhouse hospital suffering from phimosis and phagedœna of the prepuce. Dr. Alexander performed circumcision, the house-surgeon administering chloroform in the usual way. When the operation was all but completed, the patient passed a full stream of urine, which required Dr. Alexander to wait until the bladder was empty. It was then observed that the breathing had become irregular, and, in spite of every effort by artificial respiration, galvanism, &c., the patient never rallied. At the post-mortem examination nothing beyond congestion was found. It appears that the heart had ceased to beat when the breathing became irregular, and the passage of urine may have been the result of the same spasm which stopped the heart's action. The jury found that the young man had been treated skilfully, and had died under chloroform.

Liverpool, Sept. 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Ship Canal and Polluted Streams.

ON a former occasion attention has been called in these columns to a serious danger to public health that will undoubtedly arise in connexion with the polluted condition of the water forming to a large extent the future source of supply to the new ship canal, and public attention has recently been directed to this matter, by reports from one of the adjacent health authorities whose district borders upon the present Bridgewater Canal, which will ultimately become absorbed by the new watercourse. Numerous cases of a severe form of sore throat, apparently of a diphtheritic character, have arisen, to which the term "canal throat" has become applied. The directors of the canal company appear to be alive to their responsibilities, and, judging from the report of a recent meeting of the shareholders, they will endeavour to put a stop to the continued pollution of the waters of the Mersey, the Irwell, and the Medlock in their higher reaches. The Stockport Corporation has already taken steps to acquire some 100 acres of land for a sewage farm, in order to divert its sewage from the Mersey, and have notified the local authorities above Stockport, along the Mersey watershed, that they must also cease polluting the streams, so that possibly we are getting within measurable distance of the time when the present disgraceful condition of our local streams and rivers will be considerably improved.

The Hospitals.

The resignation of Mr. F. A. Heath, senior surgeon to the Royal Infirmary, has come rather as a surprise to some. Under the rules now in force every member of the honorary staff terminates his period of office at the age of sixty. Either Mr. Heath has resigned earlier than this rule calls for, or his appearance belies his real age and he carries his years remarkably well. Mr. Heath's election took place many years ago under the old rules and methods of appointment, when an election to the staff of the infirmary was almost as serious a matter to the candidates as a Parliamentary election. All that has now been changed, and the selection rests with a committee appointed for the purpose out of the general body of subscribers. Mr. F. A. Southam, who has been assistant surgeon for some six or seven years, goes up as full surgeon, and the vacant post of assistant surgeon will shortly be filled up. Amongst the applicants either Mr. Collier or Mr. Thorburn are mentioned as most likely to be the successful applicant. Both these gentlemen have been connected with the infirmary for some years.—At the annual meeting of the Ancoats Hospital a good record of work accomplished was given. This charity has in recent years made a considerable advance amongst our local hospitals, and the presence of Prince Albert Victor last year to lay the foundation of the new wing directed public attention towards it in a desirable way, for it has rather suffered in past years from the modest and unobtrusive fashion in which it has carried on its operations in one of the most crowded districts of the city. More than 10,000 patients have been under treatment during the year, a large proportion of these being accident cases. The managers appeal strongly for additional funds to clear off the debt incurred by the extensions.—A new eye hospital is projected in the neighbouring township of Altrincham; the exact need for this is not very apparent, for if every small town and district is to found a special hospital their name will soon be legion. Dr. Mules, formerly on the staff of the Manchester Eye Hospital, is to have the medical charge of the new institution.

Open Spaces, &c.

The old burial-ground attached to St. Michael's Church situate in Angel Meadow, one of the most notorious "slums" of Manchester, is about to be greatly improved and laid out as a recreation-ground for the benefit of the dwellers in that unpicturesque and squalid locality. An inquiry has been held before one of the inspectors of the Home Office, and although there was some slight opposition to the scheme, made on behalf of the churchwardens, it is highly probable that these difficulties will be got over, especially as Dr. Hoffman (the inspector) expressed his unqualified approval of the scheme.

The condition of the homes of the poor still continues to be the subject of considerable agitation, chiefly at the present time by open-air meetings, which are addressed by philanthropists, sanitarians, clergymen, and others, and we are assured that both in Manchester and Salford our municipal parliaments have the matter seriously before them. A considerable number of the worst houses have been closed or condemned and many others improved, but at present no scheme upon anything like a comprehensive scale has been brought forward for the better housing of the poor.

Our new medical officer of health, Dr. Tatham, has given public notice that he can be seen every morning from ten to twelve o'clock upon matters affecting in any way the public health, but that Wednesday afternoons will be specially set apart for this purpose, when he will be at the service of those who may wish to see him.

Manchester, Sept. 10th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Scarlet Fever in Birmingham.

DURING the past week there has been an increase in the number of cases admitted into the Borough Hospital. Forty-one new patients bring the total number up to 327. The epidemic seems to be universal, and not confined to any particular locality of the city. The Health Committee have instructed their superintendent that in case of an outbreak at a house with a shop attached the whole of the stock should be purchased and destroyed. In small tenements this may possibly succeed, but if it is repeated with large and valuable stocks, the experiment will be decidedly an expensive one. It indicates, however, that every precaution is being taken to limit the spread of this baneful disease.

The Cost of the New Workhouse Infirmary at Birmingham.

At a recent meeting of the guardians it was stated that the total cost of the building, with commissions and alterations over and above the original contract, would amount to little short of £94,000.

Prosecutions for Illegal Practice.

At the Birmingham Police-court, on the 6th inst., eighteen summonses were dealt with against various persons for falsely holding themselves out as legally-qualified practitioners in medicine and surgery. The prosecution was conducted by Dr. Showell Rogers on behalf of the Medical Defence Union. After hearing the evidence, the deputy stipendiary inflicted the full penalty and costs against three of the defendants, amounting in all to £40 and costs in each case. The other summonses were agreed to be dismissed. The pecuniary loss will probably aid in deterring this shameless kind of practice, carried on with such marked impudence. It will also help in enlightening those credulously disposed persons who, under a sense of personal guilt, are so easily trapped by specious advertisements. I am led to understand that the Nemesis of the law is not yet satisfied, and that the defendants will be further proceeded against in the County Court for the recovery of heavy penalties under the Apothecaries Act.

Birmingham, Sept. 11th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Health of Rothbury.

A WARM controversy on the health of Rothbury is going on in the Newcastle daily papers. It will be remembered that in the "Northern Counties Notes" of the 24th ult. it was mentioned that the resident medical men and the sanitary authority defended its sanitary condition, and the writer of the Notes, on the assumption that the medical men of the place would in all probability know most about it, on these grounds, and purely in a general way, to some extent supported their views. It appears that Mr. H. E. Armstrong, the medical officer of health for Newcastle, was the visitor to Rothbury who suffered in his family from the disease. Anyone going to a health resort and becoming ill from local causes is to be sympathised with. The first case in Mr. Armstrong's family took place on the twenty-first day of their visit to Rothbury—a period much beyond the usual stage of incubation of scarlet fever. Mr. Armstrong complains of the sanitary authority of Rothbury that they have no compulsory system of notification and no hospital for infectious diseases, the hardship of which he experienced when he had to remove his child all the way to the Newcastle Hospital.

Cremation.

Dr. Barron of Durham has printed the excellent address which he gave at the meeting of the North of England Branch at that city last month. In his address he chiefly deals with the cremation question, of which he is a very powerful advocate, and he certainly gives some weighty facts and arguments in favour of this mode of disposing of our dead. As bearing on the subject he narrates the following from his own observation: "In the summer of 1884 I was staying at the Lizard in Cornwall, and in the course of my wanderings found myself in the little churchyard of Landwednack, and noticed that a portion thereof was closely fenced off from the rest. I was unable to discover the reason of this at the time, but since then I have found an explanation in a little guide-book to the Lizard. It appears that in 1645 Landwednack was visited by the plague. It is said that about a century afterwards the part of the churchyard in which persons were buried who had died of pestilence was opened to receive the bodies of some shipwrecked sailors, upon which the plague reappeared. In consequence of this, that part of the churchyard was fenced off and planted, and has never been reopened since." Dr. Barron says, "If this story be true, then the germs of disease had lain in the ground, retaining their baleful influence, for one hundred years." To Dr. Barron's mind it is satisfactorily and clearly proved that the forces of nature are not capable of preventing a decaying body from causing and spreading disease when buried in large numbers in the ordinary method, especially when these bodies are buried in limited spaces, and particularly when the disease of which the person has died is of an infectious nature. He thinks that it has been proved to the satisfaction of all medical men that cremation is by far the best method for the disposal of the dead which has yet been thought of for the health of surviving humanity.

Carlisle.

At the last meeting of the governors of the Cumberland Infirmary, the Bishop of Carlisle presiding, reference was made to the very sudden death of the Secretary, Mr. Blomfield, whose desire was, the Bishop said, to do his very best for the institution he served. Mr. Blomfield gave himself up with great earnestness to the work of the infirmary.—The late Mr. Thomas Blair, whose will has been proved in the Carlisle District Registry, has left £200 to the Silloth Convalescent Institution, and £100 to the Carlisle Dispensary.—The late Miss Preusser, whose death near Windermere I have already noted, and whose interest in the boarding-out system for pauper children was well known, has left by will the half residue of her estate, which has been valued at nearly £7000, to promote that system, or for the advancement in life or possible emigration of pauper children in the district of Windermere.

Stockton Hospital.

The annual meeting of the Stockton Hospital shows an increase of patients treated as compared with the previous year; 473 in-patients had been treated, and 1265 out-door cases. The whole of the forty beds had, for the first time, been occupied, and by the new wing now in course of construction increased facilities were being provided. The subscriptions had also increased, the workmen contributing £528.

Ripon.

Last week Dr. Hoffman, medical inspector from the Home Office, made an inspection of the Ripon Cathedral burial ground, in consequence of a representation by the Dean and Chapter that the space for burials was rapidly being filled. Dr. Hoffman declared there was no pressing need for a new ground, but the Corporation, as the burial board, should be looking out for a new site.

Hexham.

The subject of the appointment of medical officer of health at Hexham has been settled by the reappointment of Dr. Maclagan, at his original salary of £300 per annum. Dr. Maclagan gives his whole time to the work, and some time since the local board wished to reduce the salary and allow private practice. This the Local Government Board did not approve of. Dr. Maclagan is, I am happy to say, rapidly recovering from his late severe accident.

Newcastle-on-Tyne, Sept. 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

GLASGOW.

Health of the City.

DURING the fortnight ending Aug. 24th the death-rate was 20·8, being 1·4 higher than the corresponding period of last year. Diarrhœa accounted for the increase; there were 51 deaths from this cause, and of these 46 occurred in children whose average age was only eight months. The total infant deaths numbered 133. Owing to the measles epidemic in the spring and infantile diarrhœa, this year will be remarkable for the large loss of child life.

St. Mungo's College.

The dissatisfaction caused by the mode of appointing the teachers in this College is not dying out, but rather spreading. Additional trouble has arisen, more particularly over the allotment of wards in the Royal Infirmary to the Professor of Clinical Medicine. The governors of St. Mungo's having appointed a professor, it became necessary to request the manager of the infirmary to accept their nominee, and provide him with wards. This request has been acceded to, and Dr. McVail has been appointed to wards as an extra physician. It is not unlikely that this dispute may be the forerunner of many such difficulties between St. Mungo's and the Royal Infirmary, two institutions which ought to have gone hand-in-hand from the outset.

Sale of Horseflesh.

It is comforting to learn from the Town Council reports, that the horse-slaughtering works of Glasgow are under constant inspection, and that "flesh of horses slaughtered in this city is never sold for human food."

Glasgow, Sept. 10th.

ABERDEEN.

Resignation of Professor Struthers.

THE University Court met on the 2nd inst., and had before it a letter from Dr. Struthers, making application to

Digitized by Google

be allowed to retire from his professorship. In his letter he says that he feels the step he has taken to be his duty alike to himself and to the University, because since a severe illness in the winter of 1887–88 he has felt unable to discharge the duties of the chair with regularity and efficiency. Referring to the changes in the School and the work that has fallen to him since he took office in 1863, he points out that he found the position to be an unsatisfactory one in every respect, as regards the numbers in the school, the buildings for anatomy, the museum, and other means of illustration and study. But he says, "In the event of my petition being granted, I shall have the satisfaction of leaving to my successor a large and increasing class, good anatomical buildings (completed in 1881), a large and select Museum of Anatomy, a full provision of instruments of anatomical study and research, and a large stock of drawings—in short, a fully-equipped and prosperous school of anatomy." Dr. Struthers has been engaged in the teaching of anatomy for forty-four years, and twenty-six of these have been spent in the service of the University of Aberdeen. During the year 1853–54, in the absence of the late Professor Goodsir, he discharged the duties of the Professorship of Anatomy in the University of Edinburgh. In speaking to a motion that the application be granted, Principal Geddes said: "By the announcement made, a vacancy falls to be created in one of the most important chairs in the Medical Faculty, and the University will lose the services of one of the best, most distinguished, and energetic professors.....He has not confined himself to his own department, for it is well known that there has hardly been any important movement of recent years connected with the University in which Dr. Struthers has not been both prominent and influential. Among these movements I might refer to the following as typical instances: The development of the system of local examinations, in which Dr. Struthers was the prime mover; the creation of medical bursaries, before him almost unknown; the institution of science degrees; and, though last, not least, the elaboration of our claim for extension of buildings, which has resulted in the concession on the part of the Government of an instalment of our claim. In his own field as a teacher and expounder of anatomy it would be difficult to find a rival to him, much less a superior. No one can, even as a transient visitor, pass through the anatomical rooms or look round the anatomical museum (which is his creation) without recognising in Dr. Struthers a most influential and energetic professor, and although opinion is known to differ, and differ very materially, as to his general educational policy, there can be no question that the period of office of Dr. Struthers as Professor of Anatomy will long remain a signal and marked period in the history and development of the Aberdeen Medical School." The motion to grant the application was carried unanimously.

University Class Fees.

The Court next considered a report from the Medical Faculty on the question of class fees. The report stated that, as the custom had hitherto been to charge a fee for not more than one practical class in connexion with any systematic course, the Medical Faculty recommended that meantime a fee be not payable for the winter practical surgical class, but that the fee for the summer course of operative surgery be raised to £3 3*s*. They also recommended that the fee for the classes of practical materia medica and pharmacy, practical medical jurisprudence and hygiene, be raised from £2 2*s*. to £3 3*s*. A resolution by the Medical Faculty was also read to the effect that in the event of Professor Struthers resigning the chair of Anatomy, they recommend to the Senatus that they should request the University Court to place systematic anatomy on the same footing as the other classes, the fee for a second attendance to be £2 2*s*. instead of £3 3*s*., and that the fees for practical anatomy and demonstrations, exclusive of cost of material, be so arranged that not more than £6 6*s*. in all should be payable by the students. The majority of the Court thought it inexpedient in present circumstances to enter upon the consideration of the recommendation of the Senatus, and a motion to that effect was carried. Principal Geddes thought the question should be taken up and considered at an early date, because it appeared to him that they were postponing indefinitely the completion of a very important University internal reform.

Aberdeen, Sept. 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Adelaide Hospital, Dublin.

ON Tuesday last the following cases were operated on in the theatre of the hospital by Mr. Kellock Barton, senior surgeon to the institution:—Case 1: Recurrent scirrhus of the right breast; the enlarged axillary glands caused œdema of the forearm. Two glands were removed, the hæmorrhage, as usual in these operations, being very free. Case 2: Adhesions of the shoulder-joint in a sailor, interfering greatly with the movements of the articulation. Under ether these adhesions to a great extent were broken down by forcible manipulation, but the procedure will probably require to be repeated. Case 3: Tenotomy of the tendo Achillis for club-foot in a child. Chloroform was administered, the patient coming very rapidly under its influence. Case 4: Incision made downwards over the front of the left tibia close to the head for swelling and deep-seated pain. The periosteum being opened, some carious bone was felt and a gouge applied; an abscess in the bone, which was of considerable depth, gave exit to a quantity of pus. In this hospital the patient, prior to operation, is etherised or chloroformed in an adjoining room, and then wheeled in on an operating couch to the theatre. The advantages of an arrangement of this kind are obvious.

Dublin Medical Schools Amalgamation Scheme.

Owing to some irregularity in preparing the necessary legal documents, a certain amount of delay was unavoidably caused; but it is expected that the advertisements for the new professors &c. will be issued in a few days.

Royal College of Surgeons and the outgoing Lord-Lieutenant.

Among the various addresses presented to His Excellency the Marquis of Londonderry prior to his departure from Ireland, was the following:—"We, the President, Vice-President, and Members of Council of the Royal College of Surgeons in Ireland, have learned with unfeigned regret your Excellency's determination to resign the high office confided to you by Her Most Gracious Majesty. We desire to approach your Excellency with this most sincere acknowledgment of the unvarying kindness which we have on every occasion experienced at your hands, and of our grateful recognition of the warm interest you have at all times evinced in the well-being of our College. Devoted as we are solely to the advancement of the science and art of our profession, we make them our objects, and leave the vexed field of politics untouched. Yet, as Irishmen, we are not debarred from recognising such admirable qualities as you have displayed in the fulfilment of your Viceregal responsibilities. The regret which we feel upon the present occasion is, however, in a certain measure tempered by the reflection that, although your residence as Viceroy in this country may have terminated, still, as a resident Irish landlord, you and your most amiable lady will still be in our midst, and our heartfelt prayer is that it may please Divine Providence long to preserve you both in health, happiness, and prosperity."

The late Henry H. Boxwell, F.R.C.S.I.

Mr. Boxwell, who had been one of the leading practitioners in the county Wexford for many years, died at the Infirmary House, Wexford, on the 1st inst., at an advanced age. The deceased gentleman had been upwards of half a century surgeon to the infirmary, and was generally esteemed and respected. The appointment he held will be filled up by the governors of the infirmary on the 30th inst., the emoluments of the post being £120 per annum, with a residence.

Galway County Infirmary.

The judge at the recent assizes having refused to fiat the annual presentment of £900 for the institution by the grand jury, in consequence of the governors not having acted in accordance with the writ of *mandamus* issued by the Court of Queen's Bench, the majority of the governors decided to close it for want of the necessary funds. A special meeting was held to consider the matter, when the chairman, Mr. Henry Persse, very generously announced his intention to maintain the institution for the ensuing year out of his own pocket. The resolution to close the infirmary was consequently

Digitized by Google

rescinded, and a vote of thanks passed to Mr. Persse for his kind offer.

Lunacy Accommodation in the Dublin Workhouses.

The two unions, North and South Dublin, are in the one district, and similarly supported. They contain 380 insane inmates, the accommodation at the north being decidedly inferior, particularly in the female divisions. There is a narrow, single-storeyed building, cramped in by a high wall on one side and an elevated structure on the other, containing double-bedded cells, which do not afford 330 cubic feet to each patient. It has no available corridor and no adequate supply of air, the only aperture in the cells for light and ventilation being windows not fifteen inches in diameter. Even at the South Dublin Union, where the accommodation is much better, there is scarcely half an acre of available exercise ground for over 220 patients.

The Lords Justices have sanctioned the expenditure of £2000 for the acquisition of certain lands necessary for Omagh District Lunatic Asylum; also £500 for improvements at Limerick Lunatic Asylum; and a similar amount for Enniscorthy Asylum.

Mr. Robert G. Bird, Fleet-Surgeon R.N. (retired), has been placed on the Commission of the Peace for the county of Cork.

Mr. M. A. Donnelly, of Dublin, met with an accident lately while driving in a car, and has been under the care of Mr. Stamer O'Grady. He is progressing favourably.

Dublin, Sept. 10th.

BELFAST.

The Royal Hospital.

The quarterly meeting of this charity was held on Aug. 26th, when, from the report presented, I learn that during the quarter there were treated in hospital 517 in-patients; of these, 201 were medical and 316 surgical. During the same period there were 5208 out-patients, of whom 3898 were surgical, the remainder medical. At the close of last quarter's report the hospital stood indebted in the sum of £1463 18*s.* 8*d.* Since then the receipts have been £1886 12*s.* 11*d.*, and the expenditure £2068 4*s.* 11*d.*, which brings up the indebtedness to the sum of £1645 10*s.* 8*d.* at the end of July. Professor Cuming, Mr. Fagan, and Professor Sinclair were re-elected medical attendants of the institution. There have been a larger number of in-patients and out-patients than in any previous year.

Queen's College.

For some time past the Queen's College authorities have had before them applications from a number of young ladies who desire to enter the medical classes with a view of studying for the medical profession. A meeting of the medical faculty of the College was held last week to consider this matter, when it was decided to open the classes to ladies. Already ladies have for some time been attending the arts classes, and, in arranging to admit them to the medical curriculum, the faculty were no doubt influenced by what has been done in other schools, as well as by the fact that in the Royal University ladies are eligible for the medical degrees and other honours. We believe that the new President (Dr. Hamilton) was strongly in favour of the arrangement which has just been made. The ladies, it is said, are not to be taught in separate classes, but will attend with the other students as in the Arts Faculty. I understand that the staff of the Royal Hospital are in favour of opening the practice of the hospital to women.

Belfast, Sept. 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Electricity in the Treatment of Fibroids.

DR. LUCAS-CHAMPIONNIÈRE lately presented to the Société de Chirurgie a very interesting note on the result of the action of electricity in the treatment of uterine fibromata, which he had undertaken conjointly with Dr. Danion, a well-known electrician. The conclusions of the authors, notwithstanding certain restrictions caused principally by the difficulty to obtain absolutely radical cures which remain the privilege of surgery, and the slowness of the results, are most favourable to the method, with which no other medical treatment, they say, can be compared. The patients were treated by Dr. Danion in Dr. Lucas-Championnière's ward at the St. Louis Hospital. He introduced in the method generally employed — that is to say, that of Apostoli — such modifications that they really constitute a new treatment. The intensities employed by Dr. Danion have never exceeded sixty-five milliampères, and the action has nearly always been purely intra-cervical. He thus endeavoured to demonstrate as clearly as possible the inutility of uterine action. For the punctures which are practised in such cases he has substituted a vaginal tampon, from which he obtained results far superior to those which have been observed heretofore. But it must be remarked that Dr. Danion, as a complementary measure to these new procedures, frequently reverses the current, which appears to give to the treatment a considerable activity. The greater number of surgeons who took part in the discussion which followed this communication agreed that, if surgery can alone pretend to effect radical cures, electrotherapy may certainly be placed at the head of the medical means.

Alcoholism.

For some time alcoholism has been engaging the attention of alienists, who attribute to it much of the increase of insanity. During the last fifty years, states a report submitted to the Minister of the Interior, the consumption of alcohol has trebled, and the number of lunatics has quadrupled. Crime and suicide are also steadily on the increase. In the years 1872–87 the number of suicides have increased by 55 per cent. Their proportion in regard to the population has risen from 15 to 21 per 100,000 inhabitants. Women resort less frequently to suicide than men. As shown in previous statistics, the frequency of suicide bears a relative proportion to age. Thus up to the age of forty years the propensity to suicide remains the same in women as in men, but after this period it increases regularly with age. The report of the last International Congress for the Suppression of Alcoholism, which was held in Paris from July 29th to Aug. 1st, 1889, contains the old and familar statement that criminality and mental aberration follow a march parallel with the consumption of alcholic beverages. It is also stated that the number of crimes and offences against morals is exactly in ratio with the consumption of alcohol. To the influence of the excessive use of alcohol is also attributed the degradation of the race, it being a fact that the health of children almost always suffers from the alcoholic excesses of the parents. To the same influence is attributed in part the phenomenon of the continued diminution in the population of France, more noticeable in some parts than in others, for in the wine-growing districts drunkenness is less prevalent than in those where the consumption of alcohol is relatively considerable.

The Medical Department of the Paris Exhibition.

This department has just published its report relative to its work during the months of June and July last. As has before been mentioned, the ambulance system is well organised. The stretchers are always ready to pick up patients, who are then attended to and conveyed to their own homes or to a hospital. The following statistics may be found interesting. The medical service had consumed during the two months of June and July 2 litres of ether, 20 litres of camphorated spirits, 60 litres of eau de mélisse (a kind of aromatic spirits), and 100 litres of carbolic water. Fifty mustard plasters were applied, and 300 hypodermic injections of morphia and of cocaine were practised on patients at the Exhibition. The number of dressings amounted to 1780, of which 935 were for visitors. One workman died from accident; among the visitors there were six cases of sudden death. In this period of two months 18 workmen and 490 visitors were sent to the hospital. The greater number of the injured workmen were the subjects of crushing (*écrasement*), contusions, or cuts. The indispositions have almost always had for their cause, among the visitors, indigestion and affections of the heart. There have been some cases of poisoning, and three cases produced by the ingestion of sausages and hams.

The Continental Anglo-American Medical Society.

The following is the constitution of this new Society, which has been already referred to in a former letter:— Honorary Presidents: Sir Spencer Wells, Sir Joseph Lister, Dr. Richard Quain, Professor Ball, Professor Brown-Séquard, Dr. Ricord, Dr. J. S. Billings, Dr. Fordyce Barker, and Dr. Weir Mitchell. Executive Committee: The Hon.

Digitized by Google

Alan Herbert, M.D., Dr. Faure-Miller, Dr. Chapman, Dr. Dupuy, Dr. Barnard, and Dr. T. Linn as Secretary (16, Rue de la Paix, Paris), to whom all communications should be addressed. The first general meeting of this Society will take place at the Grand Hotel, Paris, on Monday, Sept. 30th, at 5 P.M.; and the first annual dinner will also take place at the Grand Hotel at 8 P.M. on the same evening.

Paris, Sept. 10th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Dr. Wilhelm Loewenthal.

THE appointment of Professor Loewenthal to be a doctor in the French navy, with instructions to investigate cholera in Tonkin—which appointment I reported some time ago—has had a singular sequel. Paris journals found the news in German newspapers, and fell foul of the French Government for giving a Prussian the rank and uniform of a French officer. Some went so far as to hint that the German Professor might easily be a spy, who wished to go to Tonkin, under the pretext of scientific pursuits, in order to survey the land—perhaps even to make preparations for its conquest by Germany. These utterances caused such commotion among a number of naval officers and medical men that they addressed an indignant protest to the Admiralty, declaring that they would not receive a Prussian as a comrade. These circumstances induced the French Government to cancel the appointment, and Professor Loewenthal was officially informed of its decision, with the remark that "under existing circumstances his position in Tonkin would have been untenable." Meanwhile, however, the attention of the Argentine Government had been called to Professor Loewenthal, and it invited him to go to La Plata, to make a journey of investigation through that country, and report its results to the Minister of Foreign Affairs in Buenos Ayres. The Argentine Government wishes him to investigate the sanitary conditions of the country, and especially to determine whether it is in general healthy; what hygienic improvements might be introduced; what parts are best suited for colonisation by Europeans; whether Europeans would thrive best in the northern, the southern, or the central parts; whether they can not only live there temporarily, but also found families and multiply at a normal rate; what is the hygienic condition of the European settlements already existing, and what is the bodily and mental state of Europeans after a longer or shorter stay in La Plata. Professor Loewenthal has accepted the invitation and sailed for Buenos Ayres. My informant is a Paris correspondent of the *Vossische Zeitung* of Berlin.

Tuberculosis and Typhus in Munich.

Dr. von Ziemssen, the well-known head physician of the chief hospital in Munich, has recently published his observations and reflections on the decrease of tuberculosis in that city. His investigations had reference chiefly to the question as to what influence the cleansing of the soil of the Bavarian capital by sewers, which has almost banished typhus, has had on the frequency of tuberculosis. He shows that the number of deaths from tuberculosis has diminished by one-fourth during the last twenty-one years, and by one-third during the last eighteen years. Of every 100 deaths in Vienna in 1888, 23 were due to tuberculosis; in Würzburg, 19; in Frankfort-on-the-Maine and Nürnberg, 18; in Elberfeld and Leipsic, 16; in Berlin, Dresden, and Altona, 15; in Cologne and Stuttgart, 14; in Augsburg, 13; in Munich, Ratisbon, Hamburg, and Magdeburg, 12; in Breslau, 11; in Goerlitz, 10; and in Chemnitz, 9 per cent. Munich, accordingly, is one of the German cities which suffer least from tuberculosis. Von Ziemssen, however, hesitates to attribute this comparatively happy state of things to the cleansing of the soil alone. Nor can the protection which the boiling of milk, much more usual now than formerly, affords against the schizomycetes in the milk of tuberculous cows be regarded as the sole reason of the improvement; for Bollinger's most recent investigations have proved that the virus of the milk of a few such cows is counteracted by being mixed with that of many healthy ones. Von Ziemssen thinks that the improvement is due not only to the cleansing and drying of the soil on which the city stands, and to the supply of pure water, but also to the better construction of the houses, especially of the schools, the widening of the streets, and the laying out of large open spaces, plentifully planted with flowers, shrubs, and trees. In connexion with this subject, it is interesting to note, on the distinguished authority of Von Ziemssen's equally famous townsman and colleague, Professor von Pettenkofer, that twenty-eight times as many persons died of typhus in Munich in the sixth as in the ninth decade of this century, though the population has doubled in the interval. This victory of sanitary science is due to the simple facts that the city is now better supplied with drinking water, that the cesspools have been rendered waterproof and sewers have been laid, and that a central slaughter-house has been erected. These results are chiefly owing to the noble labours of the above-mentioned scientists and men like them.

The German Society for Public Hygiene.

The German Society for Public Hygiene will hold its fifteenth annual meeting in Strasburg from the 14th till the 17th inst. The transactions will be opened by a lecture on the Hygienic Condition and Arrangements in Alsace-Lorraine, delivered by the first medical official of that country, Privy Medical Councillor Dr. Krieger. This will be followed by a discussion of the proposals drawn up by a committee appointed at last year's meeting for legislation for the furtherance of house hygiene in Germany. This discussion will be introduced by Dr. Miguel, Burgomaster of Frankfort-on-the-Maine, who is one of the leaders of the National Liberal party in the Reichstag, and Professor Baumeister of Karlsruhe, one of the chief official advisers of the Government of Baden in architectural matters. On the second day the question of Convalescent Homes, at present a burning one for many German cities, will be introduced for discussion by Professor von Ziemssen of Munich and Burgomaster Back of Strasburg. After this discussion Professor Heller of Kiel will introduce the subject of the Prevention of Tuberculosis. The theme of debate on the third day will be the very important and hitherto somewhat neglected one of Railway Hygiene. The debate will be opened by Herr Wichert, Privy Councillor of Public Works in Berlin, and Professor Löffler of Greifswald, who will discuss the construction, lighting, ventilation, heating, cooling, and disinfecting of passenger carriages, the safe guarding of passengers against infection and accidents, the rendering of help in case of accidents and sudden illness, &c. The labours of the meeting will be diversified and enlivened by a banquet and the illumination of the Minster on the first evening; an excursion to Odilienberg, Mennelstein, and Barr on Sunday, the 15th, on which day there will be no formal meeting; and a social gathering of the members and their ladies as the guests of the city in the festal rooms of the Town-hall on Monday evening. Everyone who pays the annual contribution can take part in the meetings of the Society.

Berlin, Sept. 9th.

Obituary.

THOMAS KING CHAMBERS, M.D. OXON., F.R.C.P.

The death of Dr. King Chambers has taken away a man of high cultivation and of much force of character, though comparatively little known by the younger members of the medical profession. He had from bad health retired from active practice many years ago, when he was not fifty years of age. He retained, however, strongly marked intellectual faculties to within a few hours of his decease.

Dr. Chambers was born in London on Oct. 16th, 1817. His father was a metropolitan stipendiary magistrate. He was at school at Rugby under Dr. Arnold, and then went to Christ Church, Oxford, where he graduated with honours in classics. He retained a strong love of literature thus acquired, together with a certain fastidious literary taste, through life. He took a quaint pleasure in paradox, and expressed his opinions with a force and an originality highly characteristic of himself. This sometimes might put him at a disadvantage with persons who did not know him; but a strong sense of justice, an abounding probity, a vigorous intellect, and keen feelings of honour, always, and under all circumstances, at once inspired those who met him with the conviction that they were dealing with an English gentleman of no ordinary capacity and character.

Dr. Chambers became Doctor of Medicine at Oxford in

Digitized by Google

1846, having been an assiduous student in the clinical wards of St. George's Hospital—a hospital where his cousin, Dr. Chambers, the trusted friend of Queen Adelaide, and one of the most popular physicians of his time, had been, with Sir Benjamin Brodie, among his great teachers in that famous institution. He was elected a Fellow of the College of Physicians of London in 1848, was Censor in 1860, Goulstonian Lecturer in 1850, and Lumleian Lecturer in 1863. He delivered the Harveian Oration in 1871. He was much attached to the College of Physicians, and jealous in all ways for its reputation. Dr. Chambers was selected to accompany the Prince of Wales to Italy when his Royal Highness made that first experiment in foreign travels with his faithful Governor-General Bruce. He took a house in Hill-street, Berkeley-square, but moved after some time to Brook-street, where he remained till the failure of his health, of which we shall presently speak. He became physician to the then young St. Mary's Hospital, and took the deepest interest in its development and in the formation and progress of its medical school. No one who remembers his lectures on Medicine will have forgotten the faithful and philosophic exposition of all the subjects which he undertook to teach, for he had a deep sense of the responsibility of a teacher of men whom he desired to practise the great art of Physic in the temper of Hippocrates. He looked upon the duty which every man owes to his fellow-man in conformity with his own profound but manly sympathy with the sufferings and sorrows of the sick and of the poor. It would take long, and more space than we have, to show this in detail; it is enough to say, by way of illustration, that he was greatly interested and actively engaged in the "House of Charity," in Rose-street, where we believe he worked with a congenial friend (shall we not say, even then, a noble example?)—the present Sir James Paget. He was, moreover, intimate with Professor Frederick Denison Maurice, and for him gave lectures at the Working Men's College. This connexion probably influenced the strong religious convictions which abode with him through life. To this should be added, as evidence of his wide social and professional sympathies, that he became consulting physician to the Lock Hospital. He was one of the first to warmly espouse the cause of the medical education of women. He was, indeed, if not the founder, a most energetic supporter of the Henrietta-street School of Medicine. On the death of Professor Rolleston in 1881 he became the representative of the University of Oxford in the Medical Council. In that body he did not, owing to the state of his health, play as active a part as otherwise he would assuredly have done. Educational questions, especially any that bore on the higher education of medical students, were to him of all things the most congenial. His name will be found as acting on the Committee on Education which, with Professor Struthers, reported to the Council in 1888. He was chairman of the Committee on the Employment of Unqualified Assistants by Registered Practitioners. He bestowed much labour and had much correspondence on this matter, regarding it as a subject demanding very careful inquiry, and involving many considerations not at first sight obvious. His statement appended to the valuable report of the whole committee, to be found in Volume 20 of the Minutes of the Medical Council (page 47), is illustrative of his manner of dealing with such a question.

It is not possible to omit noticing, in connexion with education, Dr. Chambers' steady help in the progress of the Medical Statutes in the University of Oxford, though this is not a place for fully discussing this complex question. He aided the University in raising the old standard of examination to the position it now holds as thoroughly practical in every department. With Dr. Andrew, Mr. Teale, and Dr. John William Ogle, he spent without stint energy and time in this work. On the clinical examination especially, he was found to bestow the most scrupulous but never unreasonable or captious attention.

The principal works of Dr. Chambers consist of "Clinical Lectures"; of three volumes on questions affecting the digestive organs—viz., "Digestion and its Derangements—the principles of rational medicine applied to Disorders of the Alimentary Canal"; "The Indigestions or Diseases of the Digestive Organs functionally treated"; and a "Manual of Diet in Health and Disease." These volumes were all published prior to 1878. The first, indeed, was issued in 1855. They have all become part of medical literature; they attracted much attention in this country and in the United States. Besides these well-known writings, Dr. Chambers contributed anonymously to various periodicals many lighter works of fancy, and a large number of letters on social and philanthropic subjects. He also wrote a book on the Climate of Italy, the result of personal observation—the observation, be it noted, of an artist, closely attentive to all phenomena of external nature as well as of a shrewd and independent physician. It is well to say here that Dr. Chambers had considerable attainments as an artist in a true sense. He drew admirably from nature both in line and in colour, and chiefly in landscape. He had a fine sense of composition, and, though not confined to any school or educated by any master, his record of form and his interpretation of colour were alike deserving of notice among accomplished amateurs. Late in life he took to carving in wood, sometimes in bas-relief, and sometimes in the completely modelled figure. He executed several good medallion portraits, and took great pleasure in the interpretation of animal life. All this art work was, as might be expected, characterised by the force and energy of the man.

We have reserved to the last a few parting words concerning the ill-health and suffering with which Dr. Chambers was afflicted. It was discovered about the year 1862 that he had a popliteal aneurysm of the left leg. Before long amputation became urgently necessary. The limb was removed by Sir James Paget, other friends being with him. He assented with instant cheerfulness to this necessary verdict. The same affection appeared in the other limb, and this was saved by Sir James Paget, with Mr. T. Smith's aid, by pressure. In the interval of these two operations he manfully continued his work, including his duties as physician and lecturer at St. Mary's. But after the second procedure he retired into the country at Sunningdale; there he carried on his intellectual and artistic pursuits, going regularly to the Medical Council, to the examinations at Oxford, and also twice a week to the Hand-in-hand Insurance Office. Gradually serious disease was developed in the heart and larger vessels, and, after months of distress patiently borne, he peacefully sank at last, in full possession of all his faculties, on Aug. 15th of the present year.

The strength and cheerfulness of this strong man rested not more on a natural courage under much trial than on a never-failing, but yet silent, power of an abiding Christian faith. A widow and two daughters survive him. Of these two, the elder is married to Mr. Walter Ouless, the accomplished Academician.

LAWRENCE TRENT CUMBERBATCH, M.D. ST. AND., M.R.C.P. LOND., M.R.C.S.

DR. CUMBERBATCH, who died so suddenly on Aug. 18th, was born at Barbadoes on May 1st, 1824. He was the son of Edward Carlton Cumberbatch, a gentleman living in the West Indies on account of property belonging to his family. The original intention of his father was that Dr. Cumberbatch should join a well-known firm of merchants, but this was afterwards abandoned, and, as inclination led him to the study of medicine, he was entered as a student at Trinity College, Dublin, at the age of sixteen. His college career was marked by close application to work; but as in those days it was considered rather a matter of importance that he should become qualified to practise with as little delay as possible, he graduated B.A. in 1846, after which he studied for some time in Paris, and then, in 1848, took the membership of the Royal College of Surgeons of England, instead of proceeding to graduate in medicine. This was a matter of great regret to him afterwards, although at the time it was unavoidable. Having obtained his diploma, he immediately commenced work. He became assistant at Chipping Norton to a practitioner who had an extensive practice and held several appointments, amongst others a large union. It was here that Dr. Cumberbatch had the opportunities of obstetric work which laid the foundation of the excellent position he afterwards attained. Not only had he a large amount of work in obstetrics, but he had an extensive field for observation in general medicine, of which he thoroughly availed himself. Although at the time this work was frequently laborious, he valued it highly, and in after-life often remarked how much he owed to it. After doing this for a considerable time, an episode occurred which was the turning-point of his life. His father, being anxious that he should enter the army, and having considerable influence, succeeded in

Digitized by Google

obtaining a nomination for a commission as assistant surgeon. Accordingly, one day Dr. Cumberbatch received the news, and with it notice that he must come to London at once and report himself at the War Office. It happened that the season was over, and his uncle, to whom he had entrusted his diploma some time previously on purpose to be produced should there be a commission offered, had gone out of town. The day Dr. Cumberbatch arrived in London impressed him greatly, for it was entirely owing to his uncle's absence from town that his path in life became so very different. Repairing to the War Office, he learned, to his mortification, that he could receive no commission without producing his diploma. This was a serious blow then, for he had thrown up his work in the country in the expectation of immediately entering the army. He thought anxiously over his position, and came to the conclusion that he would settle in practice at once. Taking rooms near Lowndes-square, he waited. Having good family connexions and excellent ability, he soon secured a *clientèle*, which gradually increased until, after some years, it became so great that he resolved to throw up general practice entirely and confine himself to physician's work. Accordingly, in 1866, he took the M.D. of St. Andrews and the Membership of the Royal College of Physicians, London. The friend who induced him to devote himself to obstetric practice was the late Sir Charles Locock, who found in Dr. Cumberbatch a man of ability, and one who could be thoroughly trusted. He therefore largely availed himself of Dr. Cumberbatch's help, and was the means of throwing much work in his way. Dr. Cumberbatch, in like manner, was of great assistance to the late Dr. Cape, and also to Dr. Gream, whose obstetric practice was an extensive and fashionable one, until the time came when Dr. Cumberbatch found himself in the full tide of a very large obstetric and medical practice, for he always kept up his medical work, especially amongst children. Some time previously he had been offered the post of physician-accoucheur to a well-known lying-in hospital; but at that time he felt that he could not do justice to both a hospital and a large obstetric practice, and therefore declined the offer. He accepted, however, and held for some years, the office of physician to the Economic Insurance Office.

For many years Dr. Cumberbatch kept working at high pressure, making a very large income. About seven years ago, however, he suddenly discovered that his pulse, which had formerly been a natural one, had fallen to forty in the minute. Acting, therefore, on the advice of the friends whom he consulted, he immediately curtailed his midwifery practice, and as quickly as possible gave it up entirely, only entering the lying-in room in consultation. After the busiest time he had had for several years at the close of the season, he left London on the night of the 16th ult. to join his cousin's yacht in Scotland. Beyond being somewhat fatigued by the journey, he appeared well on arriving the following day. On Sunday, the 18th, at breakfast, he seemed in his usual excellent spirits. Soon afterwards he was seized with severe pain, which at first he attributed to indigestion, but which was evidently angina pectoris. He remarked that he had had a slight attack of the same kind the previous Sunday. The pain, however, increased, coming on in severe paroxysms, and in less than half an hour from the moment of seizure he died.

Dr. Cumberbatch is mourned by an extensive circle of friends and patients. He was a remarkable man, for, with no hospital or school at his back, he obtained one of the largest midwifery practices in the metropolis—a position which he held until he wisely determined to give up the more laborious part of his work and keep exclusively to consulting practice. Only those who have had the advantage of meeting him in consultation can know how valuable was his opinion; how thoroughly straightforward and honest he was, and of what comfort and support in difficult and complicated cases. He was a man of sound principles, upright, honourable, self-sacrificing, charitable, and kind. To his patients he endeared himself by his sympathy, as well as by his success in treating them; and those who knew him well were delighted by his bright, cheery manner, full of kindness, combined with thoughtfulness for their good. Of excellent observation and sound common sense, few could give more valuable or better advice than he upon general subjects, as well as upon those concerning his profession. One charming trait in his character was his entire freedom from professional jealousy, and his delight in assisting juniors who were starting in the race of life. To these he was every ready to stretch forth a helping hand and to give wise counsel. Although so widely known, and coming in contact with so many men, both in and out of his profession, it may be confidently affirmed that he never made an enemy.

Although a Fellow of the Royal Medical and Chirurgical Society, a member of the Pathological Society, and at one time a vice-president of the Obstetrical Society, immersed as he was so deeply in the cares and anxieties of a busy life, he never contributed to the literature of his profession. But he often stated that he intended, when he had sufficient time, to publish the results of observations made in the course of his practice. Cut off, as he was, at the age of sixty-five, in the midst of his activity, the rest to which he looked forward never came. There can be hardly any doubt, from a medical point of view, that had he been a little less self-sacrificing the end would not have been so soon.

In his home-life he was peculiarly charming: a devoted husband, a fond and affectionate father, full of forethought for those about him, he was likewise an excellent and agreeable, as well as an accomplished, companion. For, in addition to being a good classical scholar, he was well read in subjects apart from his profession, and was always thoroughly versed in the topics of the day. As a host, or at a dinner party, he was delightful, and those who have met him know what an acquisition he was, full of amusing anecdote and sparkling humour. He thoroughly enjoyed society, and, in spite of the many calls upon his time, entertained largely; indeed this, and an occasional visit to the Athenæum Club, were his chief means of recreation.

He married in 1854, and leaves to mourn him, besides his widow, two daughters, both of whom are married, and three sons.

WALTER JOHN COULSON, F.R.C.S. ENG.

WALTER JOHN COULSON, a brief notice of whose short and fatal illness appeared in our last issue, was born at Penzance in 1834. Having passed through the usual course at St. Mary's Hospital and filled the post of house surgeon and curator of the museum, he took the Fellowship of the Royal College of Surgeons in 1860, and became assistant surgeon to the hospital. At this time he was closely associated in practice with his uncle, the late Mr. W. Coulson, was assistant surgeon to the Lock Hospital, and was mainly instrumental in establishing St. Peter's Hospital for Stone, at which institution he was senior surgeon at the time of his death. For many years he was in large practice in St. James's-place before moving to Harley-street. His chief contributions to surgery were: "Stone in the Bladder, its Prevention, Early Symptoms, and Treatment by Lithotrity"; "Treatise on Syphilis"; "Case of Adhesion of Soft Palate to Posterior Wall of Pharynx following Syphilitic Ulceration, Operation," THE LANCET, 1862; "Obturator Hernia, Operation," ibid, 1863; "Remarks on Lithotrity, with Record of Fifteen Cases of Stone," *Med. Mirror*, 1864. He also edited the sixth edition of "Coulson on Diseases of the Bladder and Prostate."

Mr. Coulson enjoyed the esteem of a very large circle of friends, by whom his sterling qualities of mind and heart were greatly appreciated. To great skill in his profession he united a sympathetic temperament and a tenderness of disposition which endeared him to all with whom he was brought in contact, and everybody who came within the scope of his influence will deplore the void created by his untimely decease.

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—On the 4th inst., on the occasion of their annual Congress, the members of this Association assembled at Folkestone. Mr. S. Penfold (the mayor) received them, and afterwards opened the meeting. Mr. Hugh Alexander occupied the chair, who stated that the object of the Association was to obtain improved laws of sanitation and to elevate the standard of sanitary inspectors. A paper was read by the mayor of Hastings from Sir Edwin Chadwick, which dealt with the question of the disposal of sewage. Dr. Fitzgerald and Mr. Bateman read papers on the sanitation of Folkestone. After the meeting the mayor of the borough entertained the members of the Association and some friends to a luncheon at the Town Hall.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the First Examination for the degree of Bachelor in Medicine, held in August, the following candidates satisfied the Examiners:—

In all Subjects.—George Henry Vane Appleby, Wm. Henry Bishop, Robert Alfred Bolam, Robinson Brown, Henry King Dawson, Reginald Green, John Stratford Hall, Arthur Samuel Hedley, Norman Shaw Liddell, Benjamin May, Edward McGarity, William Ernest Peacock, Edward Vernon Peacock, James Peacock, Miles Prior, Edmund Race, Robert Sterling, B.A., L.Th.; Chas. Stewart, Samuel Short Whillis, James Powell Willis, and Geo. Jas. Williams, of the College of Medicine, Newcastle-on-Tyne; John William Henry Eyre, Guy's Hospital.

Elementary Anatomy and Physiology.—William Arthur Clayton, Wm. Wilkie Deans, William Forrest, Hugh Meyrick Jones, and George Turner Wayman, College of Medicine, Newcastle-on-Tyne.

Chemistry with Chemical Physics, and Botany with Medical Botany.—Arthur Badock, London Hospital; Thos. Bishop, Queen's College, Birmingham; Hugh Somerville Burniston, St. Mary's Hospital; Duncan James Caddy and Henry Case, College of Medicine, Newcastle-on-Tyne; Arthur Allen Fennings, St. Mary's Hospital; Chas. Forsyth and Arthur John Gardner, M.R.C.S., L.R.C.P., Yorkshire College, Leeds; Thomas George Smith Hodson, London Hospital; Daniel Noel Jackson, Thomas Francis Keenan, and Rowland Venables Lloyd-Williams, of the College of Medicine, Newcastle-on-Tyne; Gerald Lowsley, St. Bartholomew's Hospital; Gideon Wm. Barker Marsh, College of Medicine, Newcastle-on-Tyne; Francis Herbert Marson, Queen's College, Birmingham; George Edwyn Middlemist, College of Medicine, Newcastle-on-Tyne; Arthur Wm. Port, St. Bartholomew's Hospital; Lionel Litchfield Preston, Middlesex Hospital; William Ernest Rielly, University College Hospital; John Melville Ritchie, Queen's College, Birmingham; Lancelot Wm. Rolleston and Noel Florentine Rowstron, of St. Bartholomew's Hospital; Arthur Wm. Scott, Yorkshire College, Leeds; Robert Henry Sheperd, St. Bartholomew's Hospital; Harry Shore and Fredk. Hampson Simpson, of Queen's College, Birmingham; Harry Spicer, St. Bartholomew's Hospital; Fredk. Wm. Standish, College of Medicine, Newcastle-on-Tyne; Joseph B. Stephenson, Middlesex Hospital; Frank Wm. Stokes, University Coll. Hospital.

Chemistry with Chemical Physics.—Fredk. Carden Brodie, M.R.C.S., L.R.C.P., L.S.A., Middlesex Hospital; Charles Meaden, Bristol Medical School; Christopher Michael O'Brien, Trinity College, Dublin; Geo. Stephen Ware, M.R.C.S., L.R.C.P., L.S.A., Middlesex Hospital; Arthur Waldemar Brougham Warde, M.R.C.S., L.R.C.P.

Botany with Medical Botany.—Richard Pryce Mitchell, Lond. Hosp.

At the Second Examination for the degree of Bachelor in Medicine, the following candidates satisfied the Examiners:

Honours (Second Class).—Charles Forsyth, Yorkshire College, Leeds; Charles Henry Duncan Morland, M.R.C.S., L.R.C.P., St. George's Hospital; John Arthur Kendall, College of Medicine, Newcastle-on-Tyne.

Pass List.—Thomas Moffatt Allison and Eustace W. Powys Baines, of the College of Medicine, Newcastle-on-Tyne; Ernest Chittenden Bridges, St. Bartholomew's Hospital; Thomas Buckham, Alfred Cox, and Charles Vincent Dingle, of the College of Medicine, Newcastle-on-Tyne; Robert Bruce Duncan, St. Mary's Hospital; Eric France, College of Medicine, Newcastle-on-Tyne; Albert Gurney, London Hospital; Thomas Hartley, Wm. Cyril Haswell, Alfred John Hopper, Frederick Hunton, and Nicholas Magoris, of the College of Medicine, Newcastle-on-Tyne; John Pendlebury Molyneux, Owens College, Manchester; Kenneth Worsley Poole, M.R.C.S., L.R.C.P., London Hospital; William Turnbull and John Dobson Wardale, of the College of Medicine, Newcastle-on-Tyne; Arthur Waldemar Brougham Warde, St. Bartholomew's Hospital; Avery Clough Waters, M.R.C.S., L.S.A., London Hospital; Joseph Wood, Owens College, Manchester.

Licence in Sanitary Science.—William Henry Coates, M.B., M.R.C.S., L.R.C.P., L.S.A.; John Stokes, M.B. Durh.

Licence in Sanitary Science for Medical Officers of Health of Five Years' Standing.—Nicholas Hardcastle, M.R.C.S., L.S.A.; Thomas Stephen Maguire, M.D. Durh.; Edw. Sergeant, M.R.C.S. Eng., L.R.C.P. Lond.; William Dyne Steel, M.D. Aber.; Charles Robt. Straton, L.R.C.P., L.R.C.S. Edin.

MEDICAL MAGISTRATE.—Mr. John Bark, M.R.C.S., Stanley Mount, Bootle, has been placed on the Commission of the Peace for the borough of Bootle-cum-Linacre.

HUDDERSFIELD INFIRMARY.—Mr. Hanson Ormerod, of Brighouse, has just made a donation of £500 to the Building Extension Fund of the Huddersfield Infirmary.

QUARANTINE.—The British Representative at Lisbon telegraphed on the 9th inst. that eight days' quarantine had been imposed upon arrivals from Vigo, which was declared to be infected with disease of an epidemic character.

UNIVERSITY OF CAMBRIDGE: EXAMINATION IN SANITARY SCIENCE.—An examination in so much of State Medicine as is comprised in the functions of officers of health will be held at Cambridge on Tuesday, October 1st, and following days. Candidates who desire to present themselves for examination in October next must send in their applications and transmit the fees to the Rev. Dr. Luard, Registrar, University of Cambridge, on or before Sept. 26th.

VACCINATION CERTIFICATES.—Mr. John F. Staines has been appointed by the Local Government Board as a teacher of vaccination, and the certificate required by the different examining bodies can be obtained after a due course of instruction at the Public Vaccination Station, 47, Endell-street, St. Giles's, on Tuesday mornings, at 10 o'clock.

FOOTBALL FATALITY.—Thomas Spittle, a lad, of Lozells, Birmingham, was badly hurt on the 7th inst. whilst playing football on the Fentham-road Ground, Birchfield. He received a kick in the abdomen which necessitated his removal to the General Hospital. He died somewhat unexpectedly on Monday last.

DUNOON SEASIDE HOMES.—On Saturday last Lady King opened a new wing which has been added to the West of Scotland Convalescent Seaside Homes at Dunoon. The new structure has been built primarily for the accommodation of the servants, and, their old quarters being now devoted to patients, the accommodation of the Homes will be considerably increased.

LITERARY INTELLIGENCE.—Professor McKendrick's Text-book of Physiology will, we hear, be completed within a few days. The first portion, including General Physiology, was issued last year; and the second volume, containing Special Physiology, including Nutrition, Innervation, and Reproduction, will be published immediately by Messrs. MacLehose and Sons, Glasgow.

NEW COTTAGE HOSPITAL.—The Duke of Cambridge on Saturday last laid the memorial stone of a new Cottage Hospital at Shooter's-hill, near Woolwich. The new building, which is situated on a site given by the War Department, near the summit of the hill, cost £2700, of which £2350 have been subscribed. It contains two wards with ten beds.

DEATH OF A FASTING MAN.—An attempt on the part of a Frenchman at Lyons to imitate the foolish feats of such men as Succi and Merlatti, has, it is reported, had a melancholy, though hardly unlooked for, termination. The man, it appears, reached his twentieth day of abstinence from food; but his desire to continue the experiment was frustrated by death.

LONGTON COTTAGE HOSPITAL.—Sir Smith Child, in sending an additional gift to the amount of £250 towards the completion and furnishing of the New Cottage Hospital at Longton, expresses his earnest hope that efforts will be made to finish the work by freeing the hospital from all debt on the completion of the building, and that its proper maintenance will be one of the first cares of the inhabitants of Longton.

WORTHING INFIRMARY AND DISPENSARY.—At the annual general meeting of the governors of this institution the report and accounts, which were adopted, were on the whole favourable. The receipts for the past year amounted to £1672 0*s.* 4*d.* (including a legacy of £500 invested in 2¾ per cent. consols), and the expenditure to £1451 15*s.* 10*d.* The committee earnestly appealed for additional annual subscriptions to enable them to maintain the institution in its present efficient state.

ROYAL HOSPITAL FOR CHEST DISEASES.—On Wednesday last Lord Charles Bruce presided over a special court of governors of the above institution for the purpose of considering a resolution authorising the trustees to sell out a portion of the funded property of the hospital—not exceeding £6000—for the purpose of paying sundry debts incurred in building the new wing, and in necessary repairs. The chairman explained that the contractors had threatened legal action unless their claims were immediately settled. After considerable discussion the motion was agreed to by ten votes to seven.

RABIES.—According to the *London Gazette*, the number of dogs in England reported during the week ending August 24th as afflicted with rabies was 10 against none in the previous week. Of these, 1 died and 9 were killed. Of the 10 diseased animals, 4 belonged to Yorks (West Riding), 2 to Hants, and 1 each to Essex, Middlesex (excluding London), Oxford, and Sussex (Western Division). During the week ending Aug. 31st, there were 12 rabid dogs reported, all of which were killed. The distribution was as follows:—York (West Riding) 4, Middlesex (excluding London) 3, Surrey (excluding London) 2, and Hants, Kent, and London 1 each.

CAUSES OF UNFITNESS FOR MILITARY SERVICE.—According to an article in a Russian military medical journal, the number of young men liable to military service in the Kieff district who were rejected on medical grounds during the years 1883 to 1886 was more than 60 per cent. of those examined. The most frequent ground of rejection was myopia. This defect was especially common amongst Jews. The same remark applies to eruptions of the skin and of the scalp, which were also frequent causes of rejection. Another very frequent cause of rejection was hernia, and here, again, the Jews were found to be affected in this way more frequently than the Christians.

MORTALITY IN PUNISHMENT BATTALIONS.—Dr. Shishlo, a Russian military surgeon, has recently discussed the question of the cause of the high mortality which occurs in the so-called disciplinary battalions into which soldiers are sent for punishment. In these the life is harder, the duty more fatiguing, and the general conditions are less healthy; but according to Dr. Shishlo the explanation of the excessive death-rate depends not so much on these circumstances as on the fact that a number of the prisoners who form these battalions are sickly men, who, if they had behaved themselves, would have either been sent temporarily to their homes, or who would have obtained their discharge in the ordinary course, having completed their term of service.

PRESENTATIONS.—On Aug. 28th Wilford Vidal Robinson, L.R.C.P. Lond., M.R.C.S., of Hersham, Walton-on-Thames, was presented by a great number of friends and former patients, at Pinner, Middlesex, with an artistically executed address, accompanied by a cheque for a considerable sum, "as a mark of the high esteem and regard felt for him personally, and in recognition of the unfailing zeal and sympathy shown by him in professional work during seven years' residence among them."—Mr. H. T. Shapley, M.B. Aberd., L.R.C.P. Edin., M.R.C.S. Eng., has been presented by the patients of the Leamington Provident Dispensary with a handsome marble timepiece and bracket, as a token of their appreciation of his services and attention to them.

THE ORDER OF THE HOSPITAL OF ST. JOHN OF JERUSALEM IN ENGLAND.—We understand that, in addition to those members of the medical profession already on the roll of the above Order, of which the Prince of Wales is Grand Prior, the sanction and approval of the Queen, the Sovereign Head and Patron of the Order, has been given to the enrolment of the following as honorary associates:—Surgeon-Major George Allan Hutton, M.D.; Joseph Dallas Pratt, M.D.; Surgeon-General Sir Robert Jackson, C.B., M.D.; William Edmund Cant, M.D., F.R.C.S.; Fleet Surgeon Henry Charles Woods, M.D., R.N.; William Henry Platt, L.R.C.P.; Walter Pearce, M.R.C.P., M.B.; Brigade Surgeon E. D. Tomlinson, M.D.; Deputy Inspector-General Matthew Coates, R.N., M.D.; John Martin, F.R.C.S.; James Robertson Crease, F.R.C.S.; Frederick Charles Mears, M.B., M.R.C.S.; Francis Richard Cassidi, M.D.; John Pleydell Wilton, M.R.C.S.; Alexander Theodore Brand, M.D.; Christopher Childs, L.R.C.P.; Arthur Symons Eccles, M.B.; Robert Clark, L.R.C.P.; Charles Knott, M.R.C.S.; William Warman Coleman, M.R.C.S.; John Blackburn, M.R.C.S.; and Edward Atkinson, M.R.C.S.

SHEFFIELD GENERAL INFIRMARY.—The annual meeting of the governors and subscribers of the Sheffield General Infirmary was held in the board-room of the institution last week. The secretary read the ninety-second annual report, in which regret was expressed that the expenditure had exceeded the ordinary income by £965 8*s.* 9*d.* This deficiency was, however, more than covered by legacies, which had this year been exceptionally large, and had enabled the board to make additional and much-needed accommodation for the nurses, and also to give to the patients a more liberal diet, besides adding considerably to the capital account. Mr. Arthur Jackson said he would commend to Mr. Howard Vincent, M.P., whom he was glad to see present, the consideration of one of the most burning questions of the day—hospital reform,—which would come before Parliament shortly. There would probably be a Royal Commission, and he hoped Mr. Vincent would be one of the foremost in looking into the question. It was a herculean task, and wanted to be considered as much as any other question in the country. The report was adopted.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at midnight on September 11th, 1889.

Births, Marriages, and Deaths.

BIRTHS.

BEECHAM.—On Aug. 29th, at St. Mary's Villa, Huyton, near Liverpool, the wife of William Beecham, L.R.C.P., &c., of a son.

CARDWELL.—On Aug. 24th, at Kirkham, Lancashire, the wife of Thomas Cardwell, L.R.C.P., M.R.C.S., of a daughter.

COWARDIN.—On Aug. 31st, at Edith-road, West Kensington, W., the wife of Dr. Thos. G. Cowardin, late of Richmond, Virginia, U.S.A., of a daughter.

DAVIES.—On Aug. 18th, at Maisonnette, Woolston, Southampton, the wife of Surgeon A. M. Davies, Army Medical Staff, of a daughter.

ELLIOTT.—On Sept. 5th, at Monson-place, Tunbridge Wells, the wife of Thomas Elliott, M.D., of a son.

GOULD.—On Aug. 28th, at Queen Anne-street, Cavendish-square, the wife of Alfred Pearce Gould, F.R.C.S. Eng., &c., of a daughter.

JOYCE.—On Aug. 26th, at Victoria-terrace, Weymouth, the wife of Staff Surgeon Joyce, R.N., H.M.S. *Hercules*, of a daughter, stillborn.

LYSTER.—On Sept. 8th, at Coleshill, Warwickshire, the wife of Arthur E. Lyster, M.R.C.S. Eng. and L.S.A. Lond., of a son.

MOIR.—On Sept. 8th, at Leinster-square, W., the wife of Byres Moir, M.B., of a son.

O'REILLY.—At Rathmore House, Highgate, the wife of Dr. G. J. O'Reilly, of a daughter.

PATTERSON.—On Sept. 8th, at Gosport, the wife of Staff Surgeon A. Patterson, R.N., H.M. ship *Victor Emanuel*, Hongkong, of a daughter, stillborn.

PECK.—On Sept. 4th, at Gower-street, the wife of Awdry Peck, M.A. Oxon., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

ROE.—On Aug. 17th, at Amraoti Camp, India, the wife of Robert Bradley Roe, Esq., Civil Surgeon, Amraoti, of a son.

THOMPSON.—On Sept. 1st, at Priory House, Launceston, Cornwall, the wife of W. F. Thompson, M.B., of a son.

MARRIAGES.

AYMARD—WOOL.—On Sept. 5th, at St. Paul's Church, Clacton-on-Sea, John Law Aymé Aymard, M.R.C.S., L.R.C.P., of Ipswich, to Amy Constance Collins, third daughter of Bright Wool.

CHADWICK—HEMINGWAY.—On Sept. 11th, at the Parish Church, Ribbesford, Charles Stott Chadwick, M.R.C.S., L.R.C.P., of Birmingham, to Mary, eldest daughter of Richard Hemingway, Park Lodge, Bewdley, solicitor.

COLQUHOUN—LETCHFORD.—On Sept. 10th, at St. Matthew's Church, Upper Clapton, Wm. Brooks Colquhoun, L.R.C.P. Lond., M.R.C.S., of Stoke Newington-common, elder son of J. Carter Colquhoun, to Alice Jane, daughter of the late Frederick Letchford.

FAIRBANK—PEARSON.—On Sept. 5th, at All Saints' Church, Margaret-street, Hull, Henry S. Fairbank, M.B., son of John Hack Fairbank, to Beatrice Maude, daughter of Z. C. Pearson, The Park, Hull.

HAMILTON—RUSSELL.—On Aug. 27th, at St. Matthew's Church, Oakley-square, London, Henry Hamilton, M.R.C.S. Lond., L.R.C.P. Eng., L.S.A. Lond., second son of Henry Hamilton, of Falkland House, Finchley, to Lucilla Mary Elizabeth, widow of the late Phillip C. C. Russell, and only daughter of the late Odiarne Coates Lane, of Clifton, Bristol.

PHILLIPS—BAYLEY.—On Sept. 4th, at St. Andrew's Church, Plymouth, H. Astley Phillips, M.D., of Gravesend, to Catherine Bayley, widow of the late Fewster J. Bayley, Esq., and daughter of W. J. Square, F.R.C.S.

SMARTT—BEVAN.—On Aug. 21st, at Street Church, County Westmeath, Henry Warner Smartt, L.R.C.S.I., Castlepollard, son of F. W. Smartt, M.D., Ballymahon, to Anna Maria, daughter of the late Philip Bevan, M.D., F.R.C.S.I., Dublin.

STIRLING—ROGERS.—On Aug. 29th, at the Parish Church of St. Stephen's-by-Saltash, Charles Stirling, M.B., C.M., of London, youngest son of the late James Stirling, of Kirkintilloch, Scotland, to Julia, youngest daughter of John M. Rogers, of Pillmere, Saltash, Cornwall.

TURNER—LAWTON.—On Sept. 4th, at St. Paul's, Mill-hill, N.W., Nathaniel Henry Turner, M.R.C.S. Eng., L.R.C.P.Lond., of Ivy Walls, Edgbaston, second son of the late Fred. Turner, of Nizels, near Tonbridge, to Alice, youngest daughter of the late Robert Lawton, of Hough-hill, Dukinfield, Cheshire.

WALKER—ATKEY.—On Aug. 28th, at Holy Trinity Church, Kilburn, Basil Woodd Walker, M.D., son of the Rev. John Walker, M.A., of Bradwell, Suffolk, to Maud Ellen Atkey, daughter of the late John Atkey, formerly of Southsea.

WATSON—EDWARDS.—On Aug. 21st, at the Parish Church, East Budleigh, Devon, Robert Walker Watson, M.R.C.S. Eng., L.S.A. Lond., of Ladismith, Cape Colony, and Highbury New-park, London, to Jane Sarah, daughter of the late R. Edwards, Esq., of Knowle Villa, Budleigh Salterton.

DEATHS.

BOYES.—On Sept. 1st, at Lansdowne-crescent, Edinburgh, Charles R. Boyes, M.D., Retired Army Surgeon-Major, late of 60th King's Royal Rifles.

CLIFFORD.—On Sept. 3rd, at Cloonlurg, Slough, John James Clifford, M.D. Edin., late Surgeon-General (Queen's Royal) Lancers.

FLANAGAN.—On Aug. 8th, at Bangalore, of typhoid fever, Harold Edward Bickerson Flanagan, Surgeon Army Medical Staff, only son of Lieut.-Col. Flanagan, formerly of 76th and 81st Regts., aged 31.

FLEXMAN.—On Sept. 8th, at The Chase, King's Lynn, James Flexman, Esq., M.R.C.S., formerly of South Molton, Devon, and for many years Coroner of that borough, aged 72.

GILLIES.—On July 5th, at his residence, Regent Road, Dunedin, New Zealand, John Finlayson Gillies, M.D. Aber., L.R.C.S. Edin., aged 41, formerly of Melksham in Wiltshire, and of London.

HARTILL.—On Aug. 28th, at Sutton Coldfield, W. H. Hartill, M.R.C.S., L.S.A., of Walsall-road, Willenhall, Staffordshire, aged 53.

JACKSON.—On Sept. 1st, at Princess-square, Plymouth, Louis Pilkington Jackson, L.R.C.P., &c., aged 26.

KERNOT.—On Sept. 5th, at his residence, Bishnauth, First Avenue, Brighton, Charles Noyce Kernot, Esq., M.D., F.R.C.S.E., Lic. Med., &c., of Dalhousie-square, Calcutta, aged 49. Indian and Australian papers please copy.

SMITH.—On Aug. 26th, at St. Aubins, Jersey, James Edward Smith, M.R.C.S., &c., aged 31.

WILSON.—On Sept. 10th, suddenly, at the Cannon-street Hotel, David Wilson, M.D, of Brook-street, Grosvenor-square.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

OUR STUDENTS' NUMBER.

WE publish the following items in addition to, or in correction of, information given last week.

In an account of the changes in the lectures at the London Medical Schools in our last issue we inadvertently omitted those which had taken place at the London School of Medicine for Women, and also those in the staff of the Royal Free Hospital to which it is attached. Mrs. Scharlieb lectures on Diseases of Women, and is succeeded by Mr. Dawson in the joint lectureship on Forensic Medicine and Hygiene. Dr. H. W. G. Mackenzie gives Pathological Demonstrations once a week. Demonstrations in Auscultation and Percussion are given by Dr. Calvert. Mr. Berry holds classes in Surgery. Mr. Battle succeeds Mr. Barrow as demonstrator in Practical Surgery.

At the *Royal Free Hospital* Dr. Cockle has been appointed Consulting Physician, and is succeeded by Dr. Sainsbury. Dr. Calvert was appointed Assistant Physician, and later Dr. F. W. Andrewes was elected as an additional Assistant Physician in charge of out-patients. Mr. W. H. Dodd has been appointed Surgical Registrar (a new appointment), and Mr. E. C. Stabb Senior Resident Medical Officer.

Hospital for Sick Children, Great Ormond-street.—With respect to this hospital, it should have been stated that clinical teaching is carried on, courses of lectures being delivered by members of the medical and surgical staff at stated periods during the session.

Bethlem Hospital.—Students of the third year are allowed to attend the practice of this hospital gratuitously. This is in addition to the provision for Resident Clinical Assistants.

Aberdeen Royal Infirmary.—The paragraph on p. 509, contains some inaccuracies; we therefore reprint it in its correct form, as follows:—The Infirmary contains about 250 beds. Physicians: Drs. J. W. F. Smith-Shand, Angus Fraser, and Blaike Smith. Surgeons: Messrs. A. Ogston, J. O. Will, and R. J. Garden. Junior Surgeon: J. Hall. Ophthalmic Surgeon: Mr. J. Mackenzie Davidson. Pathologist: Mr. David James Hamilton. Dental Surgeon: Mr. Williamson. Treasurer and Secretary: Mr. W. Carnie. Also in the paragraph referring to the same institution, on p. 526 the first and last sentences should have been omitted, the appointments therein mentioned not having been made recently.

Dr. E. S. Nutting. — The American Medical Association, Chicago, Illinois.

DIABETIC URINE.

To the Editors of THE LANCET.

SIRS,—I should be glad if anyone could tell me what to add to diabetic urine to take the sickly smell away. After standing for some time in the chamber-vessel it becomes unpleasant.—Yours truly,

Sept. 11th, 1889. ASBESTOS.

LEPROSY IN IRELAND IN THE SEVENTH CENTURY.

FECHIN, who figures as the first presbyter named in the Third Order of Irish Saints, according to the famous catalogue given in Archbishop Ussher's "Britannicarum Ecclesiarum Antiquitates," is an interesting example of the circumstance, brought out into strong relief by Montalembert, that the early mediæval monks were the depositories and practitioners of the best medical knowledge of the time. There is, of course, much of the miraculous recorded in his name which sober history must reject; but, when all reasonable deduction has been made, a residuum of fact remains which the annalist of medicine cannot overlook. S. Fechin's sphere of activity was mainly in the West of Ireland, and according to Archdeacon O'Rorke, the historian of the County Sligo (Dublin: James Duffy and Sons), leprosy was the disease the saint was most frequently called in to cure. At Fore he was one day begged by a loathsome leper to take him in charge, and Fechin, having carried him on his back to the monastery, left him in the hospital and consigned him to the care of Themaria, wife of King Domnald, who, being promised a heavenly crown in recompense, undertook the unpleasant task. The Queen tended the patient devotedly, though some of her duties were so disgusting that, according to the Archdeacon, they had better remain in the obscurity of the old Latin biographer: "Inter alia dura ministeria leprosus, divinum amorem allegando, ab ea petivit, ut purulenta phlegmata e naribus suis proprio ore exsugat." The heroine had her reward; for (and here the miraculous comes in) "next day, when the saint was going to the hospital, he saw a globe of fire ascend towards heaven from the roof of the building, and on entering the sick room found that the man they had been nursing, and who had departed in the form of fire, was no other than our Lord Himself—the whole occurrence illustrating the truth of the words, 'Inasmuch as ye did it unto one of these the least of my brethren, ye did it unto me.' In going away the leper left behind a staff and a lump of the purest gold, with directions to the Queen to give them to Fechin, which she did, and the staff became the famous *Bachal Fechin* with which the saint is supposed to have performed many miracles through life, and which was held in great reverence after his death; but the gold he employed in building hospitals and in other works of charity." Skilfully disentangling this and such-like legends from their mythopæic drapery, Archdeacon O'Rorke accumulates a mass of evidence, corroborated from other sources, which makes it clear not only that the chief, if not the sole, practitioners in Ireland in the seventh century were monks, but that the disease they were most commonly confronted with was leprosy, wrongly supposed to have been first brought into Europe by the Crusaders.

G. F. H. (Marazion).—Probably the Medical Defence Union, the offices of which are in Edmund-street, Birmingham, would take up the case if the facts were represented to them.

Club.—The B.P. does not give the formula for Parrish's food. The quotation was correct for syr. fer. phosph.

Mr. Alfred Geo. Beale.—Compound tincture of benzoin, or tincture of guaiacum.

PROFESSIONAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—I have been in general practice for thirteen years, after holding hospital appointments of the highest order, and during the years I have been connected with the profession (over twenty years) I have never made a single professional enemy amongst my neighbours. My initials are J. J. G., well known to most West-end people. The patient I will call Y., and the medical brother of whom I complain Z. Y., suffering from double pneumonia and also heart mischief, was my patient, and I visited him daily. He went on very well under the usual treatment until Saturday, July 13th, when his wife allowed him to get out of bed and sit in front of an open window without my knowledge. On Sunday I found the patient not so well. On Monday morning the temperature was 104°, with evident signs of a return of the inflammation. I saw him again about 2 o'clock and also at 3. His breathing then was not favourable. I recommended his wife to call in a physician if she was not satisfied with my treatment. To this she did not consent, being sure that I was doing all I could for her husband. I made another call at 5.30, when, to my astonishment, the wife told me that she had had another doctor to see the patient, and that he was going to call again in the evening. Of course, under the circumstances I gave up the case at once. In the evening I received from Dr. Z. the following letter:—

"MY DEAR MR. G.,—I was called in to see a man by name Y——. That no misunderstanding should arise, I let you know this at once. I find that my interpretation of the laws of etiquette differ from that of some of my neighbours, and I much regret this; still, it is a pity that there should be any want of confidence between one man and another. Mrs. Y. did not send for me; a patient of mine, a friend of theirs, summoned me in haste. I have given digitalis &c., and promised to see him again, they undertaking in the meantime to see you. Shall I meet you there? Will you arrange this?—Yours, &c., Z."

The same evening, later on, Z. called on me, and I then informed him that he had acted not only unprofessionally but ungentlemanly, considering we were neighbours. Finding that there were many reports

Digitized by Google

set about which were detrimental to my character, I sent the following letter to Z. :—

"MY DEAR SIR,—I write to inform you that through certain circumstances which have occurred during the week with regard to Y. and your laws of medical etiquette, I shall be obliged to ask the opinion of the medical papers for the sake of my own reputation.—Yours truly, G."

I received a reply giving me leave to place it before the medical world.

From the above I would just ask if Z. was justified in seeing Y., knowing that J. J. G. was in attendance, and if Z. was only called in by one of his own patients and not by Mrs. Y., was it not his duty to acquaint me of it, and make me a *present* of his visit? Z. is a younger man than myself, and his qualifications are no better than my own? Poor Y. is no more. Not even Z.'s digitalis could keep him alive. The last day I saw Y. I was giving him digitalis and Warburg's tincture, so that Z. did not make any change of medicine. I am, Sirs, yours truly,

September, 1889. J. J. G.

*** We think J. J. G. has very good right to complain of Z. It is the first time we ever heard of a practitioner thinking it right to undertake the charge of another practitioner's patient—not at the request of the patient or his near relatives, but of a friend. Our correspondent has the satisfaction of being in the right and of having his treatment only confirmed by Z., who should have refused to see the case except in consultation with the practitioner in attendance.—ED. L.

A. L.—All sudden illnesses, such as the falling sickness, for which no cause was apparent, were attributed by the Greeks to a deity whose resentment they sought to overcome by a hymn which had the force of a charm. In the Medea of Euripides (v. 1172) Pan is supposed by the female attendant to have caused the convulsions under which the King's daughter died, until the poisoned robe and chaplet, the gift of the murderess Medea, were found to have induced the symptoms. A systematic medical commentary on the classics is still a desideratum.

"JUMPERS."

DR. BENNETT of Griqualand writes in the *South African Journal* an account of a peculiar nervous affection which is met with among the Griquas and other natives and individuals of mixed descent living in Griqualand. He suggests that perhaps the affection is similar to that prevalent amongst the French Canadians, and known there by the name of "Jumpers." Dr. Bennett says :—

> "The affection is entirely confined to the male sex, and I have never seen or heard of a case in the female. The victims of this strange form of neurosis go through the most extraordinary and grotesque antics on the slightest provocation. A whistle, a touch, a shout—anything, in fact, sudden and unexpected, will 'set them going.' Some will stiffen their limbs, make hideous grimaces, and valse about as if they had no joints in their body. Others will jump wildly about like dancing dervishes, imitating the particular sound that had acted as an exciting cause. Some, again, will make use of the most obscene expressions on a transient impulse, correcting themselves immediately afterwards, and expressing their regret for having used such language, whilst others, on the spur of the moment, will do anything they are told to do. If they should happen to have a piece of tobacco in their hand, and one should suddenly shout, 'Throw it away!' they will do so at once, running away for a short distance, and trembling all over their body. I remember one case in particular; it was that of a 'Bastard' boy, a mason by trade. He had been handed a piece of tobacco, and the person who handed it to him shouted out suddenly, 'Throw it away; it is a snake!' He first danced about wildly for a short time, and then ran away as fast as he was able; but he had not gone far when he fell down in a 'fit,' and it was some time before he recovered."

As to the probable cause of this affection, Dr. Bennett is disposed to ascribe it to the indiscriminate intermingling of the blood of different racial types, and the intermarriage of those standing in close relationship to one another.

A CAUTION.

To the Editors of THE LANCET.

SIRS,—During last week a man answering the following description has called at 8.30 in the morning at the houses of two neighbouring medical men, pretending he had come from a patient, and on the servant coming downstairs after delivering the message man and property (in one case a heavy marble clock) had gone. As he will now probably visit another district, I write to put other medical men on their guard. Aged about thirty; height, 5 ft. 7 in.; complexion pale; hair and very slight side whiskers dark; dress, black diagonal jacket suit; black, hard, round felt hat; appearance of a gentleman's manservant. By inserting this letter you will greatly oblige, Yours truly,

London, W.C., Sept. 10th, 1889. A VICTIM.

Mr. A. H. Boys.—It is difficult to give a definite opinion in the absence of knowledge of the exact facts; but on the supposition that the statement submitted to us is in the main a fair representation of the case, we think the charges cannot be considered exorbitant.

Dr. Naismith.—Yes, in an early number.

THE LATE DR. HABERSHON.

IT was our intention to publish this week a notice of the life and professional career of the late Dr. Habershon; but the sources of information being at this holiday season widely scattered, it will be convenient to defer what we trust will be a complete record until the end of the present month.

A. R. J. asks for information as to a method of preparing the labels on dispensing bottles in a surgery so that liquids do not affect them, and so that they are waterproof and can be gently washed when dirty.

H. Sherwood.—Certainly not.

THE APPROPRIATION OF PATIENTS BY CONSULTANTS.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me if it is right, after a consultation with a so-called specialist, for him (the specialist) to see, and afterwards prescribe and treat that patient to whom he was introduced, without the knowledge of the usual attendant (the introducer), and what is your opinion as to his conduct.—I am, Sirs, yours faithfully,

Sept. 2nd, 1889. F. A. MITCHELL.

*** We think that the "so-called specialist" acted wrongly, and would be the better for some special study in medical ethics.—ED. L.

Medicus.—We think there must be some mistake in the case our correspondent sends us. We should require some more detail before we could publish his letter. He does not even inform us where the occurrence took place or the name of the officer.

FALLING HAIR.

To the Editors of THE LANCET.

SIRS,—I have at present a lady patient under my care whose hair has been coming off in large quantities for some months past while being combed. I should feel much obliged if you or any of your numerous correspondents would kindly suggest a remedy for treatment of same.

I am, Sirs, yours faithfully,

Sept. 4th, 1889. SCARPA.

ERRATUM.—Our attention has been called to a slight error which occurred in our annotation headed "The Value of Medical Charities" in THE LANCET of Aug. 3rd, page 232, where the executors of the late Mr. John Griffith are described as "Mr. Samuel Clewin and Dr. Daniel Clewin Griffith," instead of *Dr.* Samuel Clewin and *Mr.* Daniel Clewin Griffith.

Clinical Lecture
ON
PYO-SALPINX,
WITH REMARKS ON THE OLD FAITH AND THE NEW REGARDING PARAMETRITIS AND PERIMETRITIS.

By JOHN W. TAYLOR, F.R.C.S.,
SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

GENTLEMEN,—I have just had occasion to remove a specimen of pyo-salpinx from a woman with subacute peritonitic symptoms. The specimen shows the association of pyo-salpinx with great enlargement of the broad ligament. This pathological connexion depends, I think, largely on the date of the disease, and it is fortunate that the operation of this morning has enabled me to remove so characteristic a specimen of the disease at its most instructive period. This period is usually accompanied by definite physical signs which have long been known clinically as evidence of an inflammatory disease common among women. The exact nature of this disease—how it commences—what are the tissues primarily attacked—all involve questions regarding which there has been for a long time considerable dispute. The specimen before us explains much that is difficult to reconcile between the old faith and the new on the subjects of parametritis and perimetritis.

Briefly stated, the old faith on these diseases was as follows:—Parametritis is an inflammation of the cellular tissue of the broad ligament; it is a common disease; it generally terminates in complete resolution; it frequently ends in abscess; it is rarely fatal. Perimetritis is inflammation of the peritoneum around the uterus and its appendages. Except for a form of very mild and limited character which has no symptoms and may be ignored, perimetritis is a rather rare disease. It is usually accompanied by grave and (so-called) septic symptoms. It is not infrequently fatal.

The new faith is as follows:—Parametritis as the name of a common disease is altogether a misnomer; it is occasionally met with, but is almost a pathological curiosity. Perimetritis is salpingitis. Salpingitis is the essential disease, which has been wrongly or inadequately labelled as parametritis or perimetritis.

This is the new faith which is gaining ground day by day. It is truer than the old faith, and the gods of the past will slowly go down before it. But there was something in the old faith which it is not well to lose—something in "parametritis" there is a danger of ignoring; and it is to this I wish to specially direct your attention. Before examining the specimen let me give you the clinical history of the case.

E. H——, aged thirty-nine, married fifteen years, having seven children, the youngest of whom was fifteen months old, and but recently weaned, was sent to me by Dr. Scott on April 17th. She had been "losing" almost continuously for three weeks, and complained of hypogastric pain. The uterus was enlarged and tender, and all the signs and symptoms were consistent with and suggestive of early pregnancy with threatened abortion. The sound was not used. Rest was advised, and viburnum prunifolium prescribed. Some temporary improvement followed, the hæmorrhage ceasing. On May 8th she returned with feverish symptoms (temperature 100°) and great increase of pain. On examination the uterus was found to be anchored by a mass on the left side of the vaginal roof. The mass was hard and tender, extending across the vaginal roof, and directly joining the uterus high up by a prominent posterior tumour, "feeling like a retroflexed fundus." This was diagnosed at the time as tubal. The patient from this date was kept entirely in bed, and every means were taken to bring about resolution of the inflammatory process, but without any good result. On May 11th she was seen at home. She had severe abdominal pain, and frequent vomiting. The temperature was higher, and the retro-uterine tumour large and exquisitely tender. Both signs and symptoms were considered indicative of pyo-salpinx. In spite of rest and appropriate treatment, the patient was evidently getting worse. The tumour, diagnosed by experienced touch as tubal, the hypogastric pain and vomiting, the febrile state—all markedly increasing during a period of rest—formed not only sufficient ground but proper ground for operative treatment. This was accordingly recommended to the patient and her husband, the nature and possible effect of the operation being fully explained. Her condition was evidently serious. Consent was readily and gratefully given, and the patient was removed to the in-patient department at Spark-hill. Two days later (after due consultation) I operated. What were the steps of the operation? The abdomen was opened by a small incision above the pubes. Then, with the forefinger of the right hand in the vagina and the first and second fingers of the left hand inside the abdomen, the prominent tumour was exactly mapped out and slowly unpeeled from the numerous adhesions surrounding it. When sufficiently liberated, the right hand was withdrawn from the vagina and thoroughly washed in clean hot water, the rest of the manipulations being abdominal only. After slight enlargement of the incision, the mass which you see was pulled out of the abdomen and its base ligatured. As the ligature was tightened the tubal portion of the pedicle was cut directly across by the ligature. I caught the divided portion with the forceps so as to keep it for a short time under observation; but the occurrence did not alarm me, nor did I expect that any further ligature of the tube would be necessary. The division of the Fallopian tube by the ligature often happens when the operation is performed during the acute inflammatory period, and I have never known any bad result attend the accident. The reason of this we shall see later on. The remainder of the base or pedicle was securely tied, and the tumour above cut off with scissors. On the left side the tube and ovary were involved in the surrounding adhesions, but were both fairly normal in size and consistency. These were removed at the same time, because it has been found that if the uterine appendages of one side have been removed for inflammatory disease the same disease is apt to return on the other side, and this occasionally within a short time after recovery from the original disease and operation. It is therefore judged unwise in these cases to allow the patient to run the risk of early recurrence and a second operation. Whether in every case of inflammatory origin this practice is sound or not may still be considered an open question, but the balance of general opinion and experience is in favour of its soundness. The pelvis and abdomen were now well washed out with hot water, the bleeding from the separated adhesions being somewhat profuse. A drainage-tube was left in Douglas's pouch, and the abdominal wound was closed with silkworm-gut sutures.

Now let us turn to the specimen removed. There is much more to be learnt from this than is involved in its relation to the operative proceedings already described. You will see it is a mass of considerable bulk, as large as a boy's fist, which in both size and shape it roughly resembles. It is not easy at first to differentiate the structures composing it. Here, however, is the Fallopian tube, the cross section of which (made by the silk ligature close to the uterus) is quite as large as a threepenny-piece. If we look closely at the cross section we shall see that this increase of size is caused solely by the swelling and enlargement of the walls of the tube, its lumen here being undilated. Furthermore, look as closely as you will, you will yet fail to see any vessel of considerable size divided. This explains the absence of serious hæmorrhage at the time of operation. The vessels of the Fallopian tube itself are always small in size. Now, if we trace the tube outwards, we shall find it increasing in size, and what should be its fimbriated extremity lost on the globular and thickened broad ligament, as the ball of the thumb may be said to be lost in the palm. Here is the abscess, not so much in the tube, though it is partially in the tube, as beneath the adhesions which have welded the outer extremity of the tube to the altered broad ligament. In many cases the abscess invades the ovary itself and is strictly tubo-ovarian, but in this case the ovary, as you see, can be entirely separated from the under surface of the greater bulk of tissue, leaving the abscess strictly limited to the Fallopian tube and broad ligament. I have divided the wall of the abscess just where the outline of the tube is lost and pus is freely escaping. The wall is thin; it might easily have ruptured here a few days later. But what is all this tissue, nearly as thick as the palm of my hand—this,

Digitized by Google

which is neither tube nor ovary—this, which you see has been cut across in a line with the cross section of the tube? This is none other than that fold of the broad ligament which in its normal state is semi-transparent. Now it is quite half an inch in thickness, and is traversed by large vessels almost as big as the radial. It is therefore this portion of the base or pedicle which needs and receives most careful ligature by the surgeon. Here, then, is the parametritis or cellulitis of the old authors still existing, coexisting with the salpingitis, breaking down into pus at the confluence of the two, so that it is difficult to say whether the abscess belongs more to the tube or more to the broad ligament. Should I have found the same condition if the patient could have waited safely to a later date? I think not. The abscess would have been larger than it is. It would probably have distended the tube to a greater degree than is now the case, but much of the swelling of the adjacent tissue would have disappeared In other words, as I have written elsewhere, the parametritis undergoes resolution; the perimetritis or salpingitis too often does not. On the other hand, it is of course possible that the abscess might continue to invade the cellular tissue. In this case the late pathology of the affection might differ considerably from its early stage, and it is because the pathological sequence is hard to retrace after repeated abscesses have formed and burst into the vagina, bladder, rectum, or externally, that the pathology of a recent case like this is so much more instructive than that of one of long duration. Even in chronic cases, however, the main seat of mischief has often been found to be distinctly tubal.

Finally, let us criticise the operation in the light of the specimen before us. Notwithstanding this mass of morbid tissue, which at first sight looks so full of irrecoverable disease, was the operation necessary? I am desirous of giving every credit to the policy of caution and non-interference, and wish to examine this question impartially, as if the work I have done myself had been done by a stranger. I am ready to acknowledge that all these changes we have noticed are undoubtedly inflammatory; that, with the exception of the abscess itself and the obliterative adhesions of the fimbriated end of the Fallopian tube, all the other pathological changes might absolutely disappear with time, leaving scarcely a trace behind them. Why, then, was the operation performed? You will remember that tubal abscess was diagnosed, and that this was already causing distinct symptoms of local peritonitis. Under these circumstances the operation was performed for two reasons: (1) to save life, and (2) to bring about a speedy recovery from the disease. I will consider these reasons separately.

First, to save life. Let me tell you of a tragic incident which happened in my practice a few months back. I was telegraphed for by a surgeon living some hundred miles away to see a patient of his who was seriously ill. The place was rather inaccessible, and I could not arrive at my destination until about midnight, having to post the last few miles of the journey. We saw the patient on my arrival. The physical signs in her case were almost a counterpart of those which I have described as present in the case before us; the symptoms were decidedly worse. Peritonitis was undoubtedly present, but there had been no vomiting for several hours, and the patient stated that she was in less pain than she had been. The history was an acute one of but little more than a week's duration. Her temperature had reached 104° F. There was no difficulty in diagnosing acute inflammatory disease of the uterine appendages on one side, with probable pyosalpinx. Immediate operation was advised, and after some consultation it was decided to carry this out early in the morning so soon as the necessary arrangements could be made. When we met a few hours later the patient was manifestly dying, her death taking place about half an hour later than the time agreed upon for operation. In this case intra-peritoneal rupture of the abscess had probably taken place, most likely before I saw the patient, for in cases of perforative peritonitis, especially when morphia has been given, the last few hours of life are often strangely free from marked symptoms, and the death appears to be one of sudden collapse. Similar cases are, unfortunately, by no means rare. Dr. Boldt of New York has recently reported some interesting and instructive examples of this disease in the *American Journal of Obstetrics* for March. The history of one of these cases is exactly similar to that which I have just related, and the fatal issue was as sudden and comparatively unexpected. The danger, then, of sudden death from pyo-salpinx is a real one—one that needs reckoning with while there is time; and it is no stretch of imagination to regard the operation for the removal of tubal abscess as one of direct life-saving importance. Doubtless it is only in the minority of cases that the abscess bursts into the peritoneal cavity, causing fatal peritonitis. But the danger of this is an unknown danger in every case. You see at once the necessary consequence: that *every case of pyosalpinx justifies operative interference*—not necessarily in all cases removal of the appendages. What is right in the practice of one surgeon may not be so in another, and sometimes the operation is full of difficulty and danger. But it certainly justifies abdominal exploration, evacuation of the pus, and, if possible, removal of the parts affected.

Side by side, however, with the purpose of saving life, another purpose only second to it in importance may well actuate the surgeon—namely, that of ensuring a speedy recovery for the patient. When life is not directly threatened by a purulent salpingitis, what happens? Adhesions form around the abscess, and when it bursts the pus finds its way into one of the natural cavities of the pelvis—the vagina, bladder, or bowel,—or slowly comes to the surface externally. What is the duration of these cases? It has often to be measured by years, and three years from the date of onset to the date of recovery has been frequently used by by gynæcologists as a fair average computation of the time involved by the natural course of this disease. The abscess is by no means always single. It is very often bilateral, and when the inflammation is severe secondary abscesses are apt to form like those around the knee-joint after purulent synovitis. In a case which interested me greatly several years ago, and of which I took careful drawings, a large abscess of the tube itself was accompanied by two separate abscesses of considerable size just beneath the peritoneum. All such cases, if not fatal, must necessarily run a very protracted course And it is this weary, anxious, painful time of chronic suffering which the operation of removal can abolish in the best and most perfect manner. If all goes well in the case we have been considering, how soon may we expect her to recover? In three weeks she will be convalescent; in six or eight weeks she will probably be doing her usual household duties at home.[1] This is surely a development of the "healing art" for which we may all be thankful, and none more so than the woman who suffers and the surgeon who ministers to her recovery.

THE TREATMENT OF SCROFULOUS GLANDS.[2]

BY FREDERICK TREVES, F.R.C.S.,
SURGEON TO, AND LECTURER ON, ANATOMY AT THE LONDON HOSPITAL.

IN the history of medical literature there is no more remarkable feature than the intermittent conflict which has been active for centuries around the terms "scrofula" and "tuberculosis." These terms have presented themselves at one time with a brilliant individuality, and at another have become blurred and lost beneath a cloud of mere verbiage. It has been shown at one period that scrofula and tuberculosis are identical conditions, and at another that they are fundamentally unlike. It has been demonstrated that both disorders are due to a neoplasm, to a septic change, to an infection, to an inherited diathesis, to a purely local process. Scrofula and tubercle have each played the part of Dromio in a pathological "Comedy of Errors." The progress of any knowledge of the subject has been obscured by theories and obstructed by conflicting statements, and in the mouths of men "tubercle" has been from time to time an untranslatable word. A recent German author has written the literary history of tuberculosis. The subject has absorbed 500 closely printed pages; and while the work contains a record of many brilliant scientific achievements, it is concerned chiefly with the handling of a once simple matter, rendered huge and unwieldly by mere flatulent discussion. Unfortunately this long period of scientific doubt has had a serious influence upon the treatment of strumous disease. Those who, on the one hand, have urged that

[1] This expectation was realised.—J. W. T.
[2] A paper read before the Harveian Society, April 25th, 1889.

Digitized by Google

scrofula is due to a tubercular process of a kind of which acute miliary tuberculosis is the finished type have discouraged all local modes of treatment on the ground that local measures cannot influence a constitutional disease. They have maintained that the meddling with strumous deposits has led to a more general infection of the body, and that an operation upon a scrofulous subject has little prospect of being surgically complete. On the other hand, it has been asserted that strumous manifestations are essentially local, that they may remain local from first to last, and that they are amenable to actual cure by no other than local means. It is necessary at the outset to make clear the position taken in the present paper with reference to these two attitudes.

All scrofulous manifestations are due to the tubercular process. It is true that in all the tubercle bacillus has not been uniformly detected; but in connexion with this point it has yet to be shown what part the bacillus plays in the process, what local conditions influence its development, to what extent it is essential to all stages of the change, and what is the possibility of its remaining undetected. The tubercular process is an inflammatory process of a peculiar type, and in the production of its special features more would appear to depend upon the pre-existing state of the tissues than upon the exciting cause of the inflammation. Injuries of precisely equal degree produce in one child simple synovitis, and in another strumous disease of a joint. It may be said that the phthisical lung, the white swelling, the carious spine, the tubercular testicle, and the scrofulous gland in the neck are all due to the same process, modified only by locality. Such diseased parts may as reasonably be termed tubercular as simple pneumonia; traumatic synovitis, acute orchitis, and the enlarged gland from a sore heel are classed as inflammatory. There is in the tubercular subject a certain tissue disposition as a rule. In the strumous this textural weakness is met with in individuals possessed of fairly defined physical characteristics, the heirs usually of certain hereditable "points," or the subjects of certain intangible weaknesses which place them in the vague category of the "delicate." Their grosser features are shown in peculiarities of the blood and lymph circulation, in a disposition to certain inflammatory states, notably to catarrh, and to other tissue habits which need not here be specified. The main naked-eye feature of the scrofulous process—so far especially as the glands are concerned—is the production of caseous matter. Caseation is very rarely indeed met with in chronic adenitis, except as the result of struma. In the latter condition it is almost constant when the disease follows a typical course. The term "caseous deposit" is frequently employed, and the fresh section of certain strumous glands gives some colour to the expression. In a strict sense, however, there is no deposit. The caseous gland has been the seat of a chronic inflammation of a very low type. Circumstances, which concern mainly the state of the blood circulation and the lymph current, have caused the inflammatory products to remain unabsorbed. These products, severed from all vascular influence, have undergone the passive physical change known as caseation. The cheesy mass is absolutely non-vascular. It can experience no further vital changes. It is little other than a foreign body in the substance of the gland. It may in time, by a simple chemical process, become calcareous, and in such condition remain for an indefinite period harmless. It may become surrounded by an area of healthy inflammatory action, and, being thus isolated and encapsuled, may, like other sequestra, be rendered innocuous. Both events, however, are rare. As a rule, the caseous nodule plays the part enacted by other foreign bodies. It excites a suppurative inflammation in the tissues which surround it, and the pus thus produced makes for the mass a way to escape. There are no grounds for stating that the cheesy deposit itself "breaks down into pus." An inert, non-vascular, helpless mass of débris cannot exhibit the phenomena of suppuration. It is a sequestrum; it imitates the career of a fragment of necrosed bone; and as a dead tissue it is ultimately cast forth from the body when the abscess which surrounds it has made its way through the skin. A gland, therefore, which is the seat of caseous change has within itself little prospect of recovery. It may remain quiescent for an unknown period, but the probability is that it will suppurate.

The treatment of scrofulous glands involves many phases and many difficulties. Although it cannot now be said, as Malcolm declares in "Macbeth, that struma is "the mere despair of surgery," it is still a fact that the disease may withstand every art which modern surgery can ply. The larger proportion of the cases, however, yield readily and most kindly to local and general measures, and even when the patient is "all swoln and ulcerous, pitiful to the eye," it is possible to claim for surgical treatment a more than occasional cure.

The *general treatment* of a case of scrofulous gland disease may be very briefly considered under the following heads:—

1. The patient should be placed under the best hygienic conditions, and in a large proportion of hospital cases this is the main circumstance in the treatment. Special benefit attends a long residence on the sea coast. Those places appear best suited for strumous disease where acres of seaweed lie exposed to the sun at low tide. Patients will often improve rapidly at Margate who have experienced no benefit from a stay at Brighton. It is well if the winter can be spent in some warmer climate, such as is afforded by the Riviera, and the summer in some suitable town upon the English coast. Among foreign health resorts Kreuznach deserves mention. Cases of widespread gland disease of a low grade improve there, and the same may be said of glands which are suppurating extensively. The place is, however, depressing, and patients who have resided there speak of their stay in Kreuznach with an air of melancholy.

2. A large proportion of strumous patients possess a decidedly feeble circulation, which is shown by the bluish extremities, the growth of fine hair upon the limbs, the coarseness of the subcutaneous tissues, and the frequent occurrence of chilblains. Such patients present a distinct type of the scrofulous physiognomy, and good illustrations of that type are to be met with in the sodden-looking, purple-faced, clownish children who are now and then seen shuffling their chilled limbs in the ranks of a charity school parade. Such individuals require to be properly clad, and need to have the skin covered from the neck to the ankles and the wrists with wool.

3. Of the diet of the subjects of gland disease nothing need be said; and in the matter of medicines there is little beyond the well-worn circle of iron, arsenic, quinine, and cod-liver oil. Iodine, in the form of Kreuznach water, appears in many instances to act with distinct benefit. The very general administration of the syrup of iodide of iron partakes rather of the nature of a rite than of a serious feature in treatment, and probably ranks in value with the royal touch. I have not been able to ascribe any certain or specific advantage to the use of sulphide of calcium.

The local treatment embraces the following points:—

1. Any disturbance of the periphery whence the affected glands derive their lymph vessels must be dealt with as a matter of the first importance. Cases of primary infection of the cervical glands are exceedingly uncommon. In the great proportion of instances a chronic inflammation is induced in the gland by some trouble active in the area from which the lymphatics concerned arise. Many cases of strumous disease commence as a result of the pharyngeal catarrh or sore-throat incidental to certain of the eruptive fevers. Common causes of disturbance—so far as the cervical glands are concerned—are enlarged tonsils, scrofulous pharyngitis, affections of the mouth and teeth, coryza, ozæna, otorrhœa, phlyctenular ophthalmia, and eczema of the scalp. It is of little avail to attempt the reduction of an enlarged gland if an inflammation of its substance is maintained by neglected caries of the teeth or persistent sore-throat. If it be recognised that the glandular disorder is secondary, it will be obvious that the first local measure in the treatment of the case must be directed against the primary local cause. To blindly paint a gland with iodine while the eczema of the scalp which primarily induced it is left to flourish is to waste a valuable drug.

2. Specific local applications to the glands, as distinguished from the common applications in general use in surgery, have met with but discouraging success. Iodine paint is probably in nearly all cases harmful. Its reckless use is a surgical mystery, and its employment is of interest as a relic of the customs of a bygone age. Ointments often appear to have some good effect, and the benefit that attends them depends possibly more upon the rubbing than upon the composition of the unguent. Compresses of seaweed, of Kreuznach water, and of sea water act obviously as cold applications, but it does not appear that they can claim any advantage over the simple water dressing. The gland should be protected from all irritation, and from fluctuations

Digitized by Google

of temperature. These ends can be met by the use of a slender silk scarf.

3. The most important local measure consists in giving rest to the part. Rest is a primary factor in the treatment of all inflammatory conditions. The disregard of this simple means is often forcibly illustrated in the treatment of the strumous neck. A patient with an inguinal bubo in a state of suppuration is not allowed to walk, and the subject of inflamed glands in the axilla is not allowed to use the arm. Yet a child with an identical affection of the cervical glands is permitted to keep the neck in almost incessant movement. The neck of a child is seldom at rest, and the obstinacy of glandular affections of the part, and of the sinuses that result therefrom, is certainly due in very great measure to the fact that the movements of the neck are in no way restrained. The neck may be kept at rest by a simple home-made stock, or by the wood-wool collar used by Mr. W. Knight Treves at the Margate Infirmary, or by the special splint I described some years ago.[2] In children or adults with long hair this splint may be so worn as to be unobserved. Of the good effects of the treatment by rest I can speak in emphatic terms, especially in the earlier stages of the disease, and in cases where suppuration is threatening. The measure of the good result may be estimated by comparing cases of inguinal gland disease treated by rest with an equal number treated during unrestrained movement of the limbs.

4. The remaining point concerns the operative treatment of gland disease. A large proportion of the cases yield to the general and local measures already described. A not insignificant residuum remains in which operative measures have to be considered. These cases include such as have resisted a milder treatment, such as are deliberately progressing, and such as are in some stage of suppuration. Into the physical characters of the gland which will at some time or another demand operation it is out of place to enter here. It must be allowed that the caseous gland is—except in the rarest instances—hopeless, and that neither climate, nor drugs, nor splints, nor local applications will cause the mass of dead tissue to disappear. The prognosis is probably on a precise level with that in bone necrosis. When once a sequestrum has formed, it is not hasty to assume that it will be separated, and that the tissues will not resume their normal quiet until the dead matter has been got rid of. It is possible that a fragment of necrosed bone may become encapsuled and rendered for an indefinite time inert; but in advising treatment surgeons speculate little upon that possibility. Many of the operations performed upon scrofulous glands may be at once disposed of. The treatment by crushing, by solvent or irritant injections, and by the seton, may be characterised as bad. A scarcely milder criticism may be passed upon the method of treatment by cautery puncture, which I was indiscreet enough to advise in 1882. I still believe this method to be the best for evacuating pus situate in the substance of large glands, provided that no more radical measure is intended. Glands which have been treated by cautery puncture have become shrunken and have disappeared, but the measure is of very limited application and is uncertain. The removal of a diseased gland by scraping out its softened substance with Volkmann's spoon and applying the actual cautery to the wall of the resulting cavity is a procedure which is applicable to certain cases only. It cannot claim to be regarded as a general measure. It should under no circumstances be employed in instances where the skin is still sound. It is of great value in cases where suppuration has occurred, where a sinus persists, and where it would be difficult or impossible to remove the relics of the diseased gland with the scalpel. The scraping should be complete, every trace of disease should be removed, the cavity left should be dressed from the bottom, and the neck should be kept absolutely at rest during the healing process. An unsightly scar is apt to result, and it is not unusual for the cicatrix to break down once or twice before it finally heals. Operations with Volkmann's spoon are, in the case of large gland tumours, very commonly incomplete, and have to be many times repeated. When the depths of the neck are invaded with the spoon the operation must certainly be classed as dangerous. Excision of strumous glands offers the simplest, the safest, and the most certain method of treating this obstinate affection. The operation is in accord with the primary principles of surgery, is definite, and is attended with admirable results. Recent improvements in our knowledge of the treatment of wounds have rendered the operation possible, and with Mr. Treves of Margate rests the chief merit of carrying the measure into actual practice. In favour of the treatment by excision the following points may be urged: the glands are completely and cleanly removed; the wound is an incised wound; the resulting cicatrix is thin, fine, and white. If the case be dealt with early, it must be further pointed out that the local spreading of the disease from gland to gland is arrested, the mass may be removed through a simple incision before suppuration supervenes, an unsightly and characteristic scar is avoided, and the wearisome period of the expectant treatment is replaced by a measure which can claim to be final. Although glands can be removed at any period by excision, it is needless to say that the operation is the easier the earlier it is performed. The number of the glandular swellings offers no bar to the excision. From one patient I have removed eighty-four glands, all of which were caseous, while not a few were suppurating. The sooner the operation is performed, the less extensive is the area involved and the less conspicuous is the scar. The wounds should follow as far as possible the natural lines or folds in the skin of the neck, and should be horizontal rather than vertical. An incision made in the natural cutaneous line at the level of the hyoid bone may lead to a scar which becomes actually invisible. The gland should be *cut* out, not *torn* out. In the treatmert of the resulting wound stress may be laid upon the following details: All bleeding must be well arrested. The wound must not be washed out by too strong an antiseptic solution. The edges of the incision should be very carefully adjusted, and maintained in position by sutures of silkworm gut, which are removed on the fifth or seventh day. No drainage-tube should be employed if it can be avoided; if the use of one is inevitable, it should not be retained for longer than from twenty-four to forty-eight hours. The part should be dressed with sponge only, and should be subjected to sufficient direct pressure to obliterate the "cavity" of the wound. The neck must be kept absolutely rigid for not less than ten days; and to this rule no kind of exception should be made. It is impossible to carry out the two last-named propositions if the patient has greatly enlarged tonsils. For no measure which has been employed for the treatment of the strumous neck can such excellent results be claimed as attend upon the simple excision of the glands. Considering the grave complications attending the disease, the tedious path it follows, and the disfigurement it leaves, it may be permitted to regard this operation as not the least of the improvements in modern surgery.

Wimpole-street, W.

[2] THE LANCET, June 5th, 1886.

AN ESSAY ON THE

FUNCTIONS OF INDIFFERENT CELLS IN THE HUMAN ORGANISM.

BY JAMES DICKINSON.

IN the human organism, the bulk of which is made up of highly differentiated elements, there exist certain elements which show no differentiation whatever. These amœba-like cells retain even that power of movement from place to place which a cell first forfeits as the penalty of specialisation. They have a wider anatomical distribution than any other cells, either aggregated in masses of lymphoid tissue, or forming the corpuscular elements of circulating fluids, or, as errant leucocytes constituting essential though inconspicuous features in the minute anatomy of all tissues. They are called by various names: in the blood they are called white blood-corpuscles; in the lymph channels, lymph-corpuscles; elsewhere, leucocytes. What definite share these elements possess in the working of the economy is a question which, to judge from the records in some leading text-books, has not much attracted the attention of physiologists. Whatever challenge they have undergone has been exclusively in one or other of their several characters, and even in such instances their functions have been but slightly investigated. A muscle-cell is a muscle-cell all the body over, and, no matter where it occurs, is recognised as an element in a peculiar tissue, having always the same peculiar

Digitized by Google

function. The amœboid elements I refer to are as distinctive (in contrast with the specialised elements which make up the bulk of the body) as the elements of any tissue. But they have not received recognition as being themselves elements of a tissue—a tissue presumably performing the same kind of function in all its distribution just as the tissues constituted by muscle-cells, cartilage-cells, or nerve-cells perform respectively their own peculiar functions wherever we may find them.

It may safely be assumed that undifferentiated cells or leucocytes have a normal function in the body, and also that it is worth while to inquire what that function is. It cannot be conceived that there exists in the body a tissue which has not a function, nor surely a function which is unworthy of study. Leucocytes differ from amœbæ in this, that they are not independent organisms but items in a community. In this cell community it is seen how each cell lives its own life in a way that is useful to the rest, the difficult ideal being attained of serving its own and its neighbours' ends and the whole community at one and the same time. Is the leucocyte an outcast in this ideal community? Is it the one selfish individual, living only for the indulgence of its own habits? If so, surely it must have perished in the long struggle for existence, and have paid the inevitable penalty that waits on all products of evolution for which Nature in her further developments has no need. Evolution as it concerns organisms in their mutual relations is but a gross naked-eye result of a process whose true seat is in ultimate elements. As regards the gross result, it is known that an organism epitomises in its development the whole course of development from the primitive unicellular organism up to its own point in the scale. Meanwhile within the organism is being epitomised the whole course of cell-evolution through the various stages of cell-differentiation. But in any particular organism only those stages of cell-evolution obtain permanence which are of use to that organism. Accordingly we may not only rest assured that leucocytes have a function, but we may turn confidently to their peculiar amœba-like characters for an explanation of their function, and seek in their very independence and apparent selfishness that usefulness to their fellows that justifies their existence in a community in which every cell executes a special task in the service of the whole. Moreover leucocytes, which are the representatives of the primary undifferentiated stage of cell-evolution, not only obtain permanence in the mature human organism, but form such a considerable proportion of the whole cell community as to suggest the conclusion that their function is one of great importance. For it must be remembered that lymphoid tissue, made up mainly of undifferentiated elements, has a most extensive distribution, being diffused throughout the whole alimentary and respiratory tracts, forming the main constituent of the so-called lymphatic glands, and being largely present in the red marrow of bones and in the spleen; that every artery, vein, and lymphatic vessel is a channel through which a constant stream of undifferentiated elements is passing; and, lastly, that among the elements of every other tissue isolated cells of this type are always found wandering. Not only have these amœba-like elements been treated with neglect during their lives, but their dead bodies, under a new name—pus,—are often despised and hated, or at all events regarded with suspicion. Because they are concomitants of danger they are treated as the cause of it. The same reasoning might with equal justice be used to bring dishonour upon soldiers that have died in defence of their State. That leucocytes are deserving of more consideration than they get, living or dead, it is the object of this paper to show.

There occurs in Professor Michael Foster's Text-book of Physiology (1884 edition) the following statement: "While we are able to attribute to the numerous red corpuscles an important respiratory function, we are unaware at present of any special work carried on by the scantier white corpuscles while they are being hurried along in the blood current. As far as our present knowledge goes, they seem to tarry in the blood only on their way either to be broken up or to pass into the tissues." The qualification "while they are being hurried along in the blood current" might lead one to infer that the above confession of ignorance did not apply to leucocytes that were *not* "being hurried along in the blood current." However, nowhere else in Foster's Text-book can I find any suggestion as to the functions of these cells, and I am forced to regard the statement as containing all his views in the matter. The concluding sentence quoted is apparently intended to convey two alternative suggestions—namely, that the destiny of the white cell is either to be broken up or to pass into the tissues. It seems on the face of it highly improbable that there exists in the body a tissue whose *function* is to be broken up. Death usually does not begin till function ends. However, Foster presses the matter further, and refers to the probability that it is by the death and splitting up of white blood-cells that the fibrin factors are set free in shed blood. He then offers the speculation that by a precisely similar process fibrin factors are habitually discharged into normal circulating blood, the white cells being then broken up to provide food for the tissues. It certainly would be a satisfaction if we could turn to useful account some of the results that have been obtained through so much toil and controversy in the investigation of the phenomena exhibited by shed blood in coagulation. The speculation Professor Foster offers is clearly an effort in this direction. But the speculation has the striking objection that the only function it provides for the white cells is a post-mortem one. During life it seems they have nothing to do but, like sheep in a pasture, to fatten and await the appointed hour of slaughter. We are to believe that Nature is at pains to create these cells and endow them with the precious energy called life, not with a view to making use of that energy, but simply with the object of using their dead frames when the energy has gone out of them. Food has got to be supplied to them during the term of their existence, and its potentialities dissipated as so much absolute waste. It is far from being denied here that, after the white cells have lived their life and done their work, portions of their worn-out carcases may be reutilised in the body as nutriment. That all cells are liable to a similar fate is, indeed, part of the conception afterwards to be unfolded. But it is hard to believe that Nature, the economiser, would create any cell for that purpose alone. However, it is not for man to dictate limitations to her, so let us ask the question, Is there any proof that the white cells are specially charged with this post-mortem function? Not a shadow of proof. Professor Foster himself makes the admission that the most careful examinations have failed to show that fibrin, or the essential fibrin factors, are normally present in circulating blood. Their presence, though it would be no proof of the theory under discussion, would at least be consistent with it. Their absence absolutely negatives it, unless we make the unwarranted assumption (as Foster suggests) that these substances, as fast as they are freed, are made away with in some mysterious fashion. We do indeed, by the help of the word "intra-molecular," endeavour to understand how the tissues hide away oxygen for use at leisure in the process of respiration. Here, however, we have good reason for the conception. But we should not, in the absence of the very strongest evidence, be justified in supposing that such complicated molecules as that of fibrinogen are in the same fashion habitually hidden away in circulating blood. Much less should we be justified in resorting to such a conception because a highly improbable and absolutely unsupported theory requires it.

There is no course but to reject the first of Professor Foster's suggestions with regard to the functions of leucocytes (in their character of white blood-corpuscles). Let us turn, then, to the second. But this is not a suggestion as to function at all, for it amounts to no more than the statement that white blood-cells become errant leucocytes. In the pursuit of the matter the Professor contents himself with just referring to the migration and aggregation of leucocytes in inflamed areas, and so leaves it. Whether some useful end may not be aimed at by this very migration and aggregation is a question which he might have asked himself with a view to generalising from the answer as to the usefulness of leucocytes at all times. It is a question which has been debated by pathologists, and many think satisfactorily answered. But it does not seem to have occurred to anyone that in that answer, if correct, must lie the secret of the habitual functions of leucocytes. Pathological phenomena are merely illustrations of physiological truths. A physiologist applies an irritant to the cut end of the vagus nerve in a rabbit, and, getting a certain result, deduces conclusions as to the function of that nerve. It is merely a case of altering the conditions under which a function is performed, and getting, in consequence, an exaggerated manifestation of the function. The process of inflammation is just such a simple experiment. What happens is this. An area of

Digitized by Google

tissue sustains damage. Thereafter white cells coming into the damaged area, in possession of all the powers proper to them and thinking only of their duties, begin to behave in a striking and noteworthy manner. Evidently this is in response to an alteration caused by the injury of the surrounding conditions into which the white cells enter. Do they leave their proper functions and engage themselves in a manner new to them? No more than, in the physiological experiment just mentioned, those ganglia in which the vagus nerve ends act in an altogether new fashion when the condition transmitted through the vagus suddenly alters. In both, I apprehend, there is produced an exaggerated manifestation of normal function. Every cell knows its own work and no other. It occupies itself with this all its life, and, slave to its conditions, accomplishes it with more or less success as these conditions vary. It is like an "automatic" musical instrument with one tune, whose governing conditions are transmitted, let us say, through a handle. The tune may be variously modified through alteration of those conditions, but as long as the instrument can work it will produce that tune and no other. The cells of a tissue perform the only tune they know in a manner varying as the governing conditions vary. If those conditions suddenly allow (or compel) them to perform with more energy than usual, then is an opportunity for us to detect what before may have escaped our observation; then is the time to record their tune, so to speak; and when conditions revert to the normal, we may know that the same tune is in performance, though haply inaudible. White blood-cells entering a damaged area forthwith exhibit remarkable activity. The fair inference is, that in that area some condition of restraint has been removed or some necessary condition more freely supplied enabling them to carry on their functions with unwonted vigour. If it can be determined what precise work the leucocytes accomplish, or at all events aim at, in inflammation, I shall venture, on the grounds above given, to deduce from this particular instance conclusions as to the general uses of leucocytes in the economy.

Views of inflammation take one of two tendencies. One is, to regard it as an effort of repair directed against the effects of an injury (including in the word injury whatever morbid cause is competent to evoke inflammation). The other is to regard it as a true effect of injury, requiring to have measures of repair directed against itself rather than having a beneficial tendency. The latter view aims at as purely physical an explanation as possible. But undoubtedly every vital phenomenon is a physical consequence of certain material being placed under certain conditions, and to demonstrate the physical *rationale* is not to come to the end of the matter. For every vital process in the body has an aspect which is not physical but purposive, and the object aimed at throughout is the conservation of the organism. The success with which this object is attained is the criterion of health, and in any disease whatever I believe we may see the same efforts towards the same end, however futile. That inflammation is a sequence to injury inevitable and explicable on physical grounds is quite consistent with its being a physiological effort of repair. A physical mechanism underlies all the functions that make up the economy, and the astonishing thing is that so marvellously is the mechanism of the body balanced that any derangement whatever entails by still physical mechanism compensative consequences. So, though it be right to refer the phenomena of inflammation to a "molecular change" in the wall of the bloodvessels, it is equally right to regard the process as a function responding to a need left by injury. What that need is and how inflammation copes with it are suggested in the following passage, taken from Charles Hilton Fagge's Text-book of Medicine: "It seems to me that when a part is injured, the removal of damaged tissue elements is an essential preliminary to the work of reconstruction and repair. I have for years past ventured to teach that the emigration of leucocytes in inflammation serves this especial purpose of clearing away such portions of injured structure as are no longer fit to remain. Leucocytes have been seen to take up granules of vermilion, milk globules, and particles of myelin when these substances have been placed in their way. May we not assume that they can also remove damaged cells or fibres?" That they not only can but do effect such removal is proved by the fact that the separation of sloughs is effected by their agency or that of their immediate products, which eat through the slough's attachments, and substitute themselves instead. Fagge, in adducing this fact, shows that it was observed forty years ago by Professor Goodsir. We cannot deny inflammation the merit of serving a useful function in this case. The need is obvious, and migrated leucocytes undoubtedly cope with it. Surely this is but a magnified example of a function inflammation is designed always to perform. Suppose, instead of a visible mass, just a few cells are rendered useless beyond recovery. Is it not extremely probable that the separation of irreparably damaged cells from the reparably damaged cells to which they are connected is as essential for local recovery as is the separation of an obvious slough for restoration of the part to which it is connected? And if it be so, one does not see how the separation is to be effected either by the damaged cells themselves or by their less damaged neighbours. On the other hand, it is easily seen how the separation may be effected by the aggregation of leucocytes in the part, for the properties of these cells are just such as to qualify them for the duty. It is a matter of observation that leucocytes seize upon all material that submits itself, flowing round inert particles in the manner of an amœba, carrying them off, and subjecting them to a process of intra-cellular digestion, or depositing them in a new situation. This rapacity has earned for them the name "phagocytes." Again, there is a fact which Fagge mentions—namely, that infiltration of leucocytes has always for its concomitant the disappearance of material that occupied the situation before their ingress. The material is said to be "absorbed," but the expression is, in this case and many others, only a vague equivalent for "taken up by leucocytes." This is certainly what it means in the connexion about to be referred to.

(To be continued.)

REMARKS ON THE MAYBRICK TRIAL.

BY WM. CARTER, M.D., LL.B., B.Sc., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL SOUTHERN HOSPITAL, AND PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AT UNVIERSITY COLLEGE, LIVERPOOL.

MANY questions of interest were raised at the Maybrick trial; space will allow only two or three to be discussed here.

Mr. James Maybrick, a cotton merchant, aged fifty, died on May 11th, 1889, after two short illnesses, the cause of his death, in the opinion of Dr. Humphreys and myself, who attended him, being arsenical poisoning. His wife, a young, highly-educated, and fascinating woman, was charged with murdering him, and, after a trial lasting seven days, was convicted and sentenced to death on Aug. 11th, the sentence being ultimately commuted to penal servitude for life. "What were the symptoms displayed by the deceased which caused you to come to this conclusion?"—i.e., of death from irritant poisoning, most probably arsenic—was a question asked me by the coroner. My reply was: "Very urgent and continued vomiting, diarrhœa, straining, incessant thirst, a sensation as of choking, gradual failure of the circulation, as shown by the white hand, followed by rapid sinking and early death."

I saw Mr. Maybrick for the first time on May 7th. The vomiting, which had been so excessive that for an entire day not even a drop of water could be retained, was then passing away and diarrhœa commencing; urination was free; the throat was red, dry, and glazed; there was an incessant attempt to hawk up an imaginary hair; thirst was intense; the tongue was furred; and, though the breath was quite sweet, the patient complained (to use his own words) that his mouth was "as foul as a midden"; there was also great restlessness. Such were the positive symptoms. Negatively, there was neither cramp, conjunctivitis, nor pain in the stomach or abdomen. Beyond the gastritis there was no evidence of disease.

Further facts stated to me were that the digestion had been first seriously disturbed on April 27th, on his dining at a friend's house after attending the Wirral races; that after a few days' treatment he was well enough to go to his place of business, but not well enough to resume his ordinary food, a midday meal prescribed by Dr. Humphreys being sent to him from his home and warmed at his office; that on

Digitized by Google

Friday, May 3rd, this food, from having, as he thought, been made with inferior sherry, had reinduced the gastric disorder. That was all. I did not know until much later that Mr. Maybrick had vomited on the *morning* of the races, and that he had attributed this vomiting to an overdose of some aperient medicine. We decided that his illness had been originally caused by *some* irritant food or drink. *What* we could not tell: but we did not suspect intentional poisoning. The first serious question is, whether we ought to have done so on that evidence. I think not. Husband and wife were apparently on affectionate terms with each other. The illness originally commenced, as was believed, away from home, and the symptoms seemed capable of an innocent interpretation. On the 9th I saw him again. His condition was practically the same, with the addition of tenesmus, which had been very bad all night. On the 10th, though he expressed himself as being almost well, the pulse had risen from about 84 to 108, and his right hand was white to the knuckles. On the morning of the 11th he was delirious, and in the evening he died.

I was told for the first time on the 9th that in the middle of April Mr. Maybrick had been able to eat any ordinary food during a visit to his brother's house; that he soon became sick on returning home; that this contrast had been the subject of remark and had been noticed before; that there had been a most serious estrangement between husband and wife; that the wife was known to have been unfaithful; and that just before the illness she had procured many fly-papers. We did not at once take these statements for granted; we tested them very carefully. But while still shrinking from the terrible conclusion that the murder of a husband by his wife was being attempted, we could not help feeling that, if what was stated to us was true, much that had been obscure might be cleared up, and that it was at least our duty to be very vigilant and to surround the patient with efficient safeguards. On this day some Neave's food was examined by me, and found to be pure. On the 10th something was introduced by Mrs. Maybrick into Valentine's beef juice, intended for, but not taken by, her husband; and on the 11th, the day of his death, this was proved to be arsenic. On the evidence thus far obtained a certificate of the cause of death was refused, and Mrs. Maybrick was arrested. One by one additional facts came to light, and ultimately the case stood thus: A gentleman of fairly good general health became suddenly ill on two very definite occasions. Each time he attributed his illness to something that he had taken: the first time, to an overdose of medicine; the second, to some badly prepared food. A few drops of the medicine left in the bottom of the bottle, and a thin scale of the food dried on to a washed-out jug, were found on analysis to contain arsenic. The food was sent to him by his wife; the bottle was accessible to her; similar bottles found at his office were free from arsenic; his wife had expressed her loathing of him, and had very strong reasons for wishing him out of the way; she was known to have prepared an arsenical solution; she was known also to have actually put arsenic into food intended for him; the symptoms and the post-mortem appearances were believed *by all who witnessed them* to be those of an irritant poison; and arsenic was found in his liver, intestines, and kidneys in such amount as to warrant Dr. Stevenson in the belief that the whole body contained nearly a fatal dose at the time of death.

To meet the above serious facts and inference it was alleged by the defence that the symptoms were *not* those of arsenical poisoning, but actually pointed away from it; that the post-mortem appearances strengthened this conclusion; that the patient had been in the habit of taking arsenic, and that what was found in his body might have been a portion of a long antecedent dose; and, lastly, that what was found in his food might possibly have come from a glaze in the pan, though Mr. Davies had boiled distilled water in a similar pan without getting a trace. There was no explanation of how the arsenic got into his medicine, and Mrs. Maybrick herself explained its presence in the beef juice.

The symptoms were in some respects anomalous, and in one respect—the lateness of the onset of diarrhœa—markedly so. Around this question of anomaly an interesting discussion arose. If anomalies are much commoner in arsenical than in other kinds of poisoning, and if in any given case the symptoms are like those caused by arsenic, then the fact of there being anomalies will rather strengthen than weaken the presumption that arsenic did, in fact, cause them. That anomalies *are* common in arsenical poisoning was admitted on both sides. The difference was that Dr. Stevenson did, and Dr. Tidy did not, consider them commoner than in other cases of poison compared with the actual number of such cases, or, as Dr. Tidy stated, "there are infinitely greater numbers of cases of arsenical poisoning than any other, and the result is that the anomalies become more apparent in the case of arsenical poisoning than in any other."

But is this so? The only way of determining it is by an appeal to facts, and no facts in support of the statement were offered at the trial. I had collected for use in court, if required, all the cases of poisoning that had occurred at the Royal Southern Hospital during my nineteen years' tenure of office as physician. They are 102, and not one of them was from arsenic. A similar collection from the reports of *many* institutions would help to settle this question one way or the other. But there is another method. From the number of deaths from arsenical poisoning as recorded by the Registrar-General we can infer the number of cases, as we do in deaths from disease. From the five last published volumes (from 1883 to 1887 inclusive) I have collated the deaths from the commoner poisons in England and Wales during those years. They are as follows: opium, 646; lead, 438; carbolic acid, 332; prussic acid, 132; oxalic acid, 120; strychnine, 106 (and vermin-killer, 59); hydrochloric acid, 90; cyanide of potassium, 74; phosphorus and lucifer matches, 71; alcohol, 66; chloral, 52; arsenic, 51; sulphuric acid, 49; ammonia, 45; nitric acid, 29; salts of mercury, 26. This does not support the statement that "there are infinitely greater numbers of cases of arsenical poisoning than any other."

One of the anomalies was the late onset of diarrhœa. A preliminary remark must be made here. Diarrhœa, as I stated at the trial, had certainly begun on the 7th. This symptom was mentioned to me on that day. I asked to see a motion, and Dr. Humphreys and I went to the bathroom for the sole purpose of seeing a large loose one which had been retained for examination. (We had examined the urine in the bedroom, and had been told that no vomited matter had been saved.) Not only, therefore, was the onset of diarrhœa, though admittedly late, earlier than the defence alleged, but tenesmus *followed*, and did not, as was also alleged, *precede* it. It is as well to remember here also that the patient had had no food whatever on the 4th, and very little on the 5th and 6th, and that directly the stomach became able to retain more food, diarrhœa, though never an urgent symptom, was more marked.

Can any reasonable explanation of this late appearance of diarrhœa, other than the empty intestine, be suggested? A remark made by Orfila and Tardieu in their official report on the death of the Duc de Praslin is worth reproducing here: "L'un de nous a démontré, par des expériences récentes, qu'à l'aide de faibles doses d'un composé opiacé, on parvient à diminuer les vomissements et à en retarder l'apparition, à rendre les douleurs moins aiguës et à prolonger la vie." Now it is a very striking fact that one of the first things done by Dr. Humphreys on the 28th was to introduce a morphia suppository. This was done to allay pain, but one of its effects would be to delay diarrhœa. Again, on the night of May 8th, when called up on account of the tenesmus, he ordered an opium suppository. "Why was not this urged at the trial?" may be asked. I do not know. All I know is that I drew attention to what I believed to be its importance.

Another anomaly was the slightness of the abdominal pain. Had the morphia and opium no effect in causing this? It at any rate was one of the effects (delayed diarrhœa being another) which Orfila and Tardieu say that they produced by giving opium; and as opium was given here, unless we are to suppose that it produced no effect at all, the natural inference is that it produced the effect which it was likely to produce, and which experience had shown that it did produce. It is not certainly known in what form the arsenic was administered, but most likely it was in solution. If so, this also would modify the symptoms. A strong reason for thinking that a solution of arsenic was originally used was that a solution was certainly introduced into the beef juice which was meant to be given.

Another interesting point raised was as to how long after a serious dose of arsenic had been taken it could be easily

Digitized by Google

found in the urine. The following question was put by Sir C. Russell to Mr. Paul: "Taking Dr. Humphreys' account of what he did—that he put the urine over the flame of a lamp for two minutes until he brought it to the boiling point,—I want to ask you whether, if a serious, a fatal, dose had been administered within, I would say, a fortnight of that time, there must, in your judgment, have been a deposit shown upon the copper?" Answer: "There must, in my judgment." Then, that there might be no mistake about what was meant, Sir Charles added: "I mean taking the test which Dr. Humphreys described that he imperfectly made?" "Yes." Cases bearing upon this point, where the analysis has been made by competent men, should therefore be valuable. The Duc de Praslin took a fatal dose of powdered arsenic on Aug. 18th, and died at 4.35 P.M. on the 24th of the same month. The urine passed in the night of the 21st contained a little arsenic; that passed on the 24th, none. The analysts were Chevallier, Orfila, and Tardieu; and, commenting on the absence of arsenic on the 24th, the two latter remark: "Nous devons dire que ce résultat négatif n'a rien qui doive surprendre. L'un de nous a signalé depuis longtemps ce fait, à savoir: que l'on peut trouver de l'arsenic dans l'urine à telle époque de l'empoisonnement et ne pas en déceler plus tard." The circumstances surrounding the Duc de Praslin's case, and especially the closeness with which it was watched and reported on several times daily, give great value to the recorded facts, and it is remarkable how many resemblances there are between them and those of Mr. Maybrick's illness. The Duke took poison in the afternoon or evening of the 18th. Vomiting commenced about 10 P.M. on the same day. On the 19th, on leaving a bath, there was one involuntary evacuation of the bowels. On the 20th there was no action, and no pain in the abdomen either with or without pressure, but the extremities were very cold. On the 21st, at 5 A.M., there was still no abdominal pain, no vomiting or retching, very urgent thirst, and the pulse was 80 to 85. In the evening the abdomen was distended and a little painful; no vomiting; no stool; constriction of throat severe. On the 22nd there was neither nausea nor vomiting; there were two stools *following enemata;* abdomen distended and painful to the touch; burning from throat to anus. In the night fainting occurred, and there was complete insomnia. On the 23rd the symptoms were intensified; no stools; no urine. On the 24th death took place at 4.35 P.M. The lateness of the abdominal pain, the late onset and, with the exception of the motion after the bath, very moderate character of the diarrhœa, the absence of cramps and of conjunctivitis, the sleeplessness, the coldness of the extremities, and the long interval between the fatal dose and death, are curiously similar in the two cases. The Duc de Praslin lived six days; Mr. Maybrick eight.

Liverpool.

A CONTRIBUTION TO THE

MORPHOLOGY OF THE SACCHAROMYCETE OF DIABETIC URINE.

BY J. BARKER SMITH, L.R.C.P.

THE case of diabetes which furnished the study of this saccharomycete terminated fatally after a few years, and was that of a young Jewess. The specific gravity of the urine and the percentage of sugar were fairly constant throughout, the former approximating to 1044, the latter to 4½ per cent. It was the appearance of some fusiform particles in the urine under the microscope, these slightly undulated and with a double contour, that invited an investigation which was continued over two years. I conjectured that they might have passed through the epithelium of the kidneys,[1] but it was not until I had grown aerial forms that their history became apparent, and that they were recognised as the broken segments of mother cells or spores, which differed, again, from those afterwards grown by me in not losing their double contour by immersion.

Four phases in the morphology of this saccharomycete may be mentioned:—(*a*) *Torula phase:* Settling like heavy yeast on the bottom of the vessel containing the urine, the aceto-amide reaction with iron increasing; during this period the fungus might be mistaken for a micrococcus or micrococcous form of bacterium ureæ, &c. (*b*) *Mould phase:* Throwing up hyphæ above the surface of the urine or culture solution, the hyphæ being first white, then yellowish or brown, or, under certain conditions of light and culture, pitchy black. (*c*) *Differential phase:* Resting on the bottom of the vessel for several weeks under starved conditions, the vessel containing water only. Both clavate and globular terminal cells may be observed, from which escape smaller round cells without nuclei, but with a few pinkish cells between them. Barrel cells are also present, apparently formed by conjugation. (*d*) *Aspergillus phase:* Growing well on moistened bread, forming a dark greenish grey or canescent patch, which becomes bluish olive green when treated with spirit or ether. This phase is interesting because it is an example of one of the facts which enable us to conclude that the physiology of the larger fungi is somewhat explanatory of that of the smaller. The aspergillus form, for instance, may be traced to a lower or micrococcous form, whilst its extracts exhibit some of the constituents of the larger fungi. This analogy I purpose treating more at length in a future paper; there are numerous interesting developments connected with the simple facts here stated.

The urine evaporated gave a gummy opaque mass, surrounded by crystalline granules of modified uric acid. The ethereal extract recovered by spirit and diluted with water exhibited in a few days hyphæ growing above the solution. A sample of urine acidulated with hydrochloric acid and agitated with ether afforded two layers, the upper one clear and the lower one turbid. The clear layer gave a semi-crystalline extract, containing two organic forms, one subspherical and the other fusiform (débris of mother cells). The turbid layer gave a clear gummy extract, surrounded by crystalline granules and containing three sorts of organic forms, round complete cells, and débris of incomplete cells. The fungus was grown in various solutions, and the cells were found to differ in size according to the culture solution, whilst their shape varied according to position in or out of the culture solution. None of the forms, however, differed so widely as to be indistinguishable. The most constant characters of the aspergillus forms of the fungus are the macroscopic appearance of the patch, the branched hyphæ supporting the spores, terminal hyphæ with constrictions supporting two terminal subspherical spores from a well-marked node or constriction (similar to the basidospores with sterigmata of the larger fungi), submoniliform appearance of other terminal hyphæ, and the double contour of the spores themselves, which contour is immediately lost on immersion in fluid. The spores become very small when grown in citric acid solution, remaining distinct, however, from the common aspergillus of lemons, which sometimes resembles a starved mucor. They grow in a 2 per cent. phosphate of ammonia solution with a somewhat larger percentage of citric acid; also in similar salts with glycerine, sugar, &c.; the mould form eventually becoming yellowish-brown, the brown or even blackish colour not being apparently distinct from the yellow except by quantity or condensation. In this form perhaps only a single central nucleus will be found, the pinkish nucleus becoming clear or of a steely-blue colour on altering the focus, whereas the aspergillus forms often exhibit in their spores two to four nuclei. Bread forms a good culture-bed for these aspergillus forms; they may be kept six months or longer in a chip-box, the spores retaining their vitality—e.g., examination of spores—after six months. Dry: Cells somewhat smaller than a blood-corpuscle; cell wall dark in colour and well marked, an outer halo and an inner pinkish one under altered focus; some with hyaline centres; others containing from three to four rose-coloured nuclei; others, again, with bluish granular contents. Moist: The somewhat oval spores become round; the double contour of the cell wall disappears and becomes evident as a dark line; pinkish nuclei become motile and are extruded as spores; cell contents become larger, but remain clear and homogenous.

SUPPLEMENT TO THE PAPER ON THE FUNGUS OF DIABETIC URINE.

In the study of the fungus of diabetes four phases in the life history of the same plant were selected. In studying other fungi than the schizomycetes, we may select these phases as types, leaving, however, the morphological history of the different fungi incomplete, and not confusing the term *micrococcous* form with micrococcus.

Torula type.—Examples may be found in the mucus from the evacuations of children suffering from autumnal catarrhal diarrhœa, in which there is a history of cold meat or some article of diet taken twelve hours before. Cells in various stages of development are found, and may be traced through several phases to the more complete endogenous mother cell, whose walls are breaking away to afford exit to the four complete daughter cells. At this moment the endogenous mother cell somewhat resembles those compact cells of four in a group found in myxœdemic and gonorrhœic urines, &c. The micrococcous form of this type is well illustrated by the mucous membranes, or even epidermis, of the gouty and the rheumatic, in their secretions and excretions, or even in the well water contaminated thereby; also by the small pink nuclei from the uvula and fauces, especially before a case of tonsillitis. In a similar way, I am persuaded, may be found in syphilis, recent or remote, those streptococcus germs like small definite specks, under a fifth of an inch, which are supposed to cause it—i.e., not only in the blood about a chancre, but also in the ventricose hair from a patch of syphilitic psoriasis, or, again, in the urine. The urine of gouty and rheumatic patients submitted to cultivation affords a variety of forms which refuse for months to grow in solutions of urea unless sugar is added, whilst growing freely in solutions of uric acid; some of these are often greenish in colour. With rheumatism and gout in view, some early experiences of mine as a fungus eater more than twelve years ago may be mentioned. I had with a companion partaken of fungus (Coprinus atramentarius) at breakfast every day for a week, when I awoke one morning with pain in my right ilium, and later on in the ankles and soles of the feet, which rendered locomotion painful; my ankles were weak, and I was nearly crippled; getting well after taking iron and discontinuing the fungus. My companion after a few days experienced the same symptoms. The experiment was again repeated in both cases, with the same result. Moreover, one of my patients had been a sufferer from apparently rheumatic pains in the calves of the legs, and was always benefited by a short course of iron. Finding he was in the habit of eating uncooked mushrooms, I advised him to discontinue his habit; he did so, and lost his pain, which he had had at irregular intervals for years, and he has remained free from them ever since. Another interesting one-celled fungus was found in the bile-stained urine of a jaundiced patient who had pain under the right scapula, and whose symptoms came on after exposure in a damp meadow in autumn. Its distinctive characters were its bright halo, apparently with ciliæ, its motility, and its small oblong pink nucleus. I think I have seen the same fungus emerging from one of the desmids, and in some cases of pneumonia in children.

I shall not attempt to illustrate the *mould* type, though I suspect some of the forms found in rheumatism and gout would enable me to do so; I will therefore pass on to those resembling aspergillus.

Aspergillus type.—In many cases where there is an aspergillus growing on the ceiling in a corner of a bedroom the inmates will exhibit various forms of irritation referable to the mucous membrane and the skin. Such are conjunctivitis, laryngeal irritation, bronchial catarrh, bladder irritability, and itching papules of the skin, often persisting for months, and especially coming on after measles; troubles of the external ear, and even attacks of epilepsy; also ringworm. A microscopical examination from the different parts affected will confirm the analogy with the aspergillus of damp paper, although we may be left with a suspicion, which is strengthened by our study of the diabetic saccharomycete, that we have in the spores of what we pass as those of bacterium ureæ possibly those of an aspergillus living under other circumstances of growth. Certainly I have sought oxalates in the aspergillus hitherto unsuccessfully; they are found in mucor, as a possible cause of the irritations of mucous membranes in such cases, which often resemble the respiratory dyspnœa and bladder irritation associated with oxalates, but I have not proved that the aspergillus contains them in any form. Of this, however, I am assured: that the larger fungi are explanatory of the smaller fungi, in physiology and in chemical constitution—e.g., the constant occurrence of tyrosine-like crystals, easily extracted by spirit, and cramming the spores of the larger fungi, &c. In poisoning by some of the larger fungi (apart from irritant resins of the russulas or the muscarin of the amanitæ) there is also much to remind one of oxalic acid and cholera. Oxalates do occur in the fungi, not only outside the hyphæ but inside; I attribute the poisonous nature of the puff-ball to this fact as much as to the ripening of the spores, for at the time when this fungus becomes yellow and poisonous, crystals of calcic oxalate crowd the hyphæ. Some of these points were mentioned by me in a letter published in THE LANCET of Aug. 30th, 1884.

An interesting case which has lately come under my care has increased my interest in oxalates, and made me consider another mode of their origin in the body in addition to idiopathic formation and ingress by the alimentary canal—viz., by the lungs,—and this, perhaps, not always wholly immediately, but indirectly through the agency of micrococcous forms. Such an experience is probably unrecorded, as the process known as the platinum process has only lately been in use, and my patient was engaged in working the process as an elegant addition to photographic art. He complained of a cough which he had had for six months, and spat blood for about two months before. He was anæmic, and complained of *general weakness*, *pain in the back*, and over the region of the heart. His temper was irritable. Sometimes he was absent in mind or self-conscious. He had sensations of heat in his head, slight giddiness, and flushing of cheeks frequently. There was no sweating at night or loss of flesh. Physical examination revealed no signs of phthisis; his heart beat irregularly and feebly, and there was a hæmic murmur. The sputa were loaded with small fungus cells, but contained no bacilli. The urine contained abundant minute crystals of calcic oxalate. He had conjunctivitis, which he had also noticed in his fellow-workers. On visiting his dark chamber, brilliant crystals of potassic oxalate glittered like small diamonds everywhere—on the floor, shelf, and bottles. The potassic oxalate is used in the process in hot saturated solution. It may be mentioned that Nägeli found that no fungus grew in oxalate of ammonia and oxalic acid except on the addition of sugar.

Dulwich.

THE HISTORY AND USE OF ANÆSTHETICS IN MIDWIFERY.

BY FRED. W. ALLWRIGHT, M.D., L.R.C.S.I.

(Concluded from p. 1242, vol. i. 1889.)

Chloroform: its mode of administration.—A good remedy will fail in its effects if not properly administered. This truism especially applies to anæsthetics, even in surgical practice, while in obstetrics care and skill are essential to the successful use of them, and out of all proportion to the attention bestowed upon the subject in the text-books. No one can be a good administrator of an agent so powerful as chloroform without a careful study of the chemical, physical, and vital principles concerned. A few of these should be clearly understood. As to the exact nature of the changes which it effects in the cells of the nervous centre it is needless to inquire. It is sufficient to know that the effect is by a direct action upon these cells, according to all authorities, and that the chemical theory of former times, which referred the action to suspended oxygenation of the blood, has been abandoned. Neither is artificial anæsthesia cerebral anæmia, although this state accompanies it. Chloroform belongs to that class of poisons which have an elective action upon the nervous system, selecting certain parts and leaving others alone. A special affinity to the nervous system is shown by the preponderating amount found in it; thus, when the amount in the blood is 1 part, there will be in the brain 3·25 and of chloroform 3·92 parts. The rapidity of the action of chloroform is an important fact. Entering the system through the pulmonary circulation, it passes directly with the blood currents to the nervous centres. In like manner, and with the same rapid action, the system clears itself, and cessation of administration ensures speedy cessation of effect. The fact enforces attention to the importance of intermittence of the inhalation. Paul Bert found that dogs in a mixture of air and chloroform vapour, which required an hour to produce insensibility, invariably died at the end of seven hours. Intermitting administration could be continued indefinitely

Digitized by Google

with safety.[1] The residual air of respiration should also be held in mind by the administrator of chloroform. The cumulative action of this agent, of which a great deal was formerly said, is only the additional effect of the amount of vapour contained in this air; in other words, the effect of chloroform will continue to be progressive after the influx of vapour by the tidal current of respiration has been stopped, until all that is in the air of the lungs and bronchial tubes has passed into the blood. The vapour of all anæsthetic agents is heavier than air, and this fact has an important bearing upon the position of the mouth and nose of the patient in relation to the surface from which it is inhaled. Temperature has a powerful influence upon the amount of vapour which the air will carry. With a change in the thermometer of 20° the amount of chloroform vapour doubles. The record of chloroform accidents shows many cases plainly due to the sudden inspiration of air heavily charged with the vapour. Essential requisites of any apparatus or plan for the safe administration of chloroform are that it shall ensure a thorough admixture of air with the vapour, also give the power of graduating the process and limiting the dose. Nature has prepared an instrument which fully meets these demands. It is a hollow or cup-shaped sponge. This article, dipped in warm water, and squeezed out, is unequalled in convenience and efficacy. It is soft and pliable; it is so porous that the supply of air cannot be shut off; if pressed together after chloroform has been sprinkled on it, every little interstice, as it gives passage to air, yields to that air its modicum of vapour. The only device at all comparable with it is Esmarch's mask, and that is not so readily carried. An essential adjunct to this sponge is a bottle which will only permit the escape of the liquid by drops. A perfume-bottle with a screw-cap tube is the best, or an ordinary perforated cork will answer the purpose. Provided with these, the administrator has perfect command over the rate of administration; while the mode almost universally recommended of pouring chloroform upon a handkerchief or napkin is faulty in the extreme; it is not only faulty, but dangerous. This is not a matter of opinion, but of facts of physics. The current of inspiration can never be equably charged with the vapour of a liquid which is poured on a cloth in patches, so that it does not pass through, but only over, the moistened surface. The patient cannot fail to get at one breath air only slightly charged with the vapour, and at another that containing a dangerous amount. There can be no doubt that many practitioners have given up the use of chloroform in obstetrics from neglect of attention to these minute points. After sprinkling a few drops of the liquid on the sponge and squeezing it together, it is applied to the patient's nose and mouth. If coughing is excited, the vapour is altogether too strong. If the pains lessen in force or cease, a few words of encouragement and little delay, and recommencement with a very small dose, will generally obviate the difficulty. When the patient shows that she is passing under the influence by expressions of relief, the sponge is withdrawn, replenished, and held closed in a folded towel to prevent evaporation. The patient will indicate, if told to do so, when a pain is approaching; then two or three deep inspirations will anticipate the suffering. The object is to keep her in the first stage of anæsthesia of authorities. There are three by Sansom: (1) sopor, (2) stupor, and (3) stertor. Campbell divides this first stage, again, into three: (1) an initial stage of amelioration, (2) incomplete analgesia, and (3) complete analgesia. But the different degrees of narcotism glide insensibly into each other. The respiration of the patient and the appearance of her countenance indicate her condition. In obstetric analgesia, and with a small amount poured on the sponge, there is no need to watch the pulse. After the patient has ceased to make voluntary remarks, a question will enable the administrator to judge of the extent of the influence by the readiness and coherency of the answer. A better description of this process has never been given than that by Channing: "The object in ordinary midwifery practice or in the severer form of labour pains in the use of etherisation[2] is to diminish suffering. There is much of this pain which is tolerated readily, and from this the patient does not demand relief from extraordinary agents. So true is this in practice that cases daily occur in which etherisation is induced, and in which the patient determines exactly its extent. In the intervals of uterine contractions the instrument is removed by the patient or by her direction given in some way, and which is at once understood. She knows when the pain is coming, and demands the inhaler. She graduates, so to speak, the supply exactly by the demand; and in this way is presented to the observation of the practitioner one of the most important and interesting agencies in operation for relieving suffering, sometimes agony, which he ever notices." As the head distends the vulva, the effect of chloroform is carried more deeply to meet the acuter suffering of this stage. Full surgical anæsthesia may be required, and is often necessary as an efficient aid in delivery of the head without injury to the perineum. The head being delivered, the administration should cease. The length of time during which the inhalation of chloroform may be continued would be difficult to determine. Paul Bert's experiments have indicated its harmlessness with small doses and an intermittent administration. In practice, Snow has continued it for thirty-one hours, Simpson fourteen hours, and Protheroe Smith twenty-eight hours. Snow is undoubtedly correct in saying that "the quantity of chloroform given in labour might be continued daily for an indefinite period without appreciable effect on the health."[3] It is evident from the foregoing that the administration of chloroform in labour is no light or easy task. To do it well requires great care, close attention, constant watchfulness, and entails no small amount of extra fatigue. Under chloroform the operation of turning is very much facilitated, and rendered possible in cases which, without it, would be impracticable. Indeed, it was in cases of neglected cross-positions that anæsthetics won their earliest and most brilliant triumphs. The most determined opponents of their use have testified to their benefits in such cases, and experienced accoucheurs have succeeded in turning under chloroform when all previous efforts had failed and every preparation had been made for embryotomy.[4] In seventeen cases of obstructed labour in women who had previously had craniotomy or embryotomy performed, version under chloroform gave nine living children and seven more with heart pulsation.[5] In proceeding to administer chloroform for version the obstetrician should be fully alive to the fact that anæsthesia must be carried very deeply. All voluntary efforts must be rendered impossible; even in the deepest narcosis, as manifested by stertorous breathing, the introduction of the hand will not always fail to excite uterine contractions. An assistant is most desirable in these cases, and should always be obtained if possible. Still, a neglected shoulder presentation at night, many miles from professional assistance, and urgently demanding relief, may present itself to the practitioner at any time. A few directions may aid in meeting the exigencies of the case. See to the placing of such assistants as may be at command, and explain what will be required of them. Place the patient in a proper position across the bed, the hips free of the edge, and take measures for her being kept there. Carry the anæsthetic deeply, and do not commence the operation until there is stertorous, or at least heavy, breathing. In committing the continuance of the administration to the hands of a non-professional person, the drop tube is a valuable resource; directions to vigorously shake the bottle will be necessary in order to get enough of the liquid; an overdose is not easy, and if the patient is on her back the accoucheur can obtain a full view of the face and watch the respiration. The imagination has not been drawn upon for such cases, and experience has taught the dependence of excess upon attention to details.

Indications.—Chloroform being in labour as an analgesic, pain is the indication for its employment. But while there is no labour without pain, it is not every labour that requires chloroform. In muscular women of the lower classes labour causes more effort than suffering. In women of nervous type, whose systems have been enervated by refinement or luxury, the suffering is apt to be acute. In all classes there are happy exceptions, in whom parturition proceeds rapidly, and the pain is not severe enough to tax the nervous system and is well borne. The necessity or advisability of chloroform to facilitate labour must rest with the obstetrician; as a means of relieving pain it should depend upon the patient. There is a general agreement amongst authorities that the proper time to commence administration is when the os is nearly opened and expulsive pains are about to begin. Whether anæsthesia has been needed previously or not, it will most

[1] Annuaire de Thérapeutique, Bouchardat, 1884.
[2] Channing uses the term "etherisation" to denote the effects of chloroform as well as ether.

likely be demanded now. The most painful period of labour is when the head distends to the utmost and clears the two existing circles of soft parts, the os and the vulva. During that part of the process in which the head is moulded to the bony canal, which sometimes requires many pains, anæsthetic effect is not so much needed, and chloroform may often be dispensed with. The stretching of soft parts, however, is often most agonising, and at the vulva relief is most urgently called for. With entire unconsciousness and complete acinesia, not only is acute suffering saved, but delivery of the head is effected with less danger to the integrity of the perineum than under any other circumstance.

Contra-indications.—It may be stated in general terms that no contra-indications exist to the administration of chloroform in labour when the severity of the pains demand it. Diseases of the vital organs and some special conditions, however, demand careful consideration.

Chloral.—The physiological effects of chloral are strikingly similar to those of chloroform. Locally it is an active irritant, in strong solutions vesicant, or even escharotic. It is also decidedly antiseptic taken internally. Its first effect is a local one upon the stomach; then follows a stage of exhilaration similar to that caused by alcohol; after this comes sleep, and then narcotism. Its action may be divided into three periods: (1) excitement; (2) hypnotism; (3) stupor. Preceding or attending the second and third stages, it exerts a decided anæsthetic action, very much diminishing any pain which may be present, but scarcely ever abolishing it. Chloral also causes marked muscular relaxation, reduces the temperature, and enfeebles the contractions of the heart. It is introduced into the system through the primæ viæ, differing in this respect from chloroform, and differing from that agent also in its effect upon the conjunctiva, producing insensibility of that membrane long before that of the skin is affected—"a unique exception, thus far, in the history of intoxicants." So similar are the physiological effects of chloroform and chloral that Liebreich, the introducer of the latter to therapeutics, formulated a chemical theory of its action, according to which chloral undergoes decomposition in the blood; chloroform is liberated and becomes the efficient agent. This theory has not been accepted. Chloral was introduced to therapeutics in 1869. In the same year it was first used in obstetrics by Simpson, who found that, while the patient was so deeply hypnotised by it as to be only partially aware that labour was going on, the uterus still continued to contract strongly and regularly.[6] In 1874 Dr. Playfair presented the claims of chloral to the profession, and has ever since been a strong advocate of its use. He urged its especial value in women of highly organised nervous type, primiparæ, and in whom dilatation of the os took place slowly and painfully. In such cases dilatation was promoted and relief rendered without the disadvantage of suspending labour, as is the case when morphia is administered. Space will not permit of giving the experience of other authorities, but a careful survey of them upon the use of chloral in labour shows a striking absence of that disagreement as to facts regarding its action which is the case with chloroform. Interference with the process of parturition was no longer a novel thing when chloral came under observation; moreover, the effect of chloral does not vary so widely with the dose, and especially it does not vary so rapidly as with chloroform. Whatever the explanation, there is general unanimity of testimony as to the effect of chloral upon the various elements and processes of parturition. 1. It is a quieter of nervous agitation, a stimulant for mental despondency, a soother of irritability, and a tolerably efficient remedy for hysterical manifestations. 2. Its anæsthetic properties are decided and considerable; nevertheless, it cannot rival chloroform in its absolute power over pain. The sufferings of labour are lessened, but unconscious delivery can scarcely take place. It has not succeeded in establishing itself in surgery as an anæsthetic. 3. The strongest and most abundant testimony is in regard to the influence of chloral in promoting dilatation of the os. It seems specially adapted for cases of thin and rigid os, when the pains are more irritating than effective. 4. Its effect upon uterine contractions is, like chloroform, regulating and tending to restore them to the normal type when they are spasmodic or irregular. In such cases it may seem to increase uterine action; most observers agree that uterine action is not lessened. 5. Muscular relaxation being a pronounced physiological effect of chloral, it would be expected to promote the passage of the head over the perineum; but there is a singular absence of testimony upon this point. The period of labour and the class of cases best adapted to the action of chloral are evident from what has preceded. In giving chloral, its irritating qualities must be kept in mind. Administered by the stomach, it should be well diluted; if by the rectum, in some bland vehicle. Fifteen grains may be given in an ounce of water, and repeated in twenty minutes, and again in forty minutes, if necessary. In repeating the doses of chloral, the fact should be borne in mind that, once given, its action has passed beyond control. In this respect it presents a marked contrast to chloroform, with which cessation of inhalation causes very speedily cessation of effects. Chloral is perfectly safe, however, with reasonable care. The contra-indications to the use of chloral are the existence of diseases of the stomach and heart.

Ether.—The influence of ether upon the duration of labour, upon the uterine contractions, and upon the maternal soft parts is not materially different from that of chloroform; there are, however, certain minor points of difference which deserve consideration, while the mode of administration differs considerably. In regard to the influence of ether upon the duration of labour, one can with this remedy blow both hot and cold. In those cases, especially in primiparæ, in which the patient is exhausted from long effort, so that not only do the abdominal muscles fail to supplement the contractions of the uterus, but the uterine muscle itself grows weak from fatigue, ether, being one of the best diffusible stimulants, will often reawaken with renewed vigour the muscles engaged in the expulsion of the child, so that the administration of this anæsthetic will often obviate the necessity of instrumental delivery. Again, in those cases in which, during the second stage of labour, each expulsive effort causes such pain that the action of the abdominal muscle is inhibited, a mitigation of the suffering by the adminstration of any analgesia will result in the active co-operation of the abdominal muscles, and consequently a more speedy termination of labour. On the other hand, in those women who from excitement and pain are stimulated to a degree of frenzy, in which, regardless of the pain they inflict upon themselves, and deaf to the expostulations of the medical attendant, they summon every atom of muscular force at their command to terminate their intolerable suffering, any anæsthetic will calm the excitement and allow the labour to take a more natural and placid course. But, in any case, ether, like chloroform, if pushed to an extreme degree, will diminish the contractile power of all the muscles, and thus not only retard labour, but predispose to post-partum hæmorrhage.

Method of administration.—After trying the familiar cone and various forms of inhalers, all more or less complicated, it will be found that the most convenient and suitable apparatus is a rather thin towel or napkin, folded once and laid lightly over the patient's nose and mouth. The ether is dropped upon the compress, only by three or four drops at a time, at the close of every expiratory act, directly below the point of the patient's nose. In this way none of the vapour is driven away from the nose and mouth by the expired air, but all of it enters the lungs at the next inspiration, and the individual is in a few seconds irresponsive to the prick of a pin or a pinch. Narcosis being established, it is sufficient to let fall only a drop or two beneath the nose at about every alternate inspiration in order to keep the patient unconscious and insensible. If this course is pursued, there will not be the stertorous breathing, frothing mouth, and deeply congested face only too familiar in many of the surgical clinics where ether is habitually administered. If ether is given as an analgesic to mitigate the labour pains, it should be administered, of course, just as the pains come on, while in the intervals the administration may be discontinued.

OPEN SPACES FOR WAKEFIELD.—The Wakefield Paxton Society intend to open recreation grounds in several parts of the city for the use of the public. Much interest is shown in the scheme, and the promoters are receiving generous support. In addition to the ground recently opened by the Society in Pinderfields-road, others have been promised by, respectively, Sir E. Green, M.P. for the city, Miss Edith G. Mackie, daughter of a former member, and by Mrs. Frederick Thompson, of South-parade.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE COCAINE HABIT.

By ARTHUR P. LUFF, M.B., B.Sc. LOND.,
LECTURER ON MEDICAL JURISPRUDENCE AND TOXICOLOGY, AND WARDEN OF THE COLLEGE, ST. MARY'S HOSPITAL; ASSISTANT PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL.

THE following case of long-continued addiction to the use of cocaine, which lately came under my notice, will probably be of interest to the medical profession.

The patient, a gentleman, consulted me for a feeling of inaptitude for work, mental indecision, occasional palpitation of the heart, and dyspeptic symptoms. I ascertained that three years ago he had been recommended to apply a 5 per cent. solution of the hydrochlorate of cocaine to the nasal mucous membrane to relieve an attack of nasal catarrh, and that he had found the result so pleasurable that he had continued the application on and off for a period of three years, quite irrespective of any catarrh or affection of the mucous membrane of the nose. At no time did he abstain from the use of the cocaine for a longer period than two weeks, and he frequently employed it daily over a period of four or six weeks. As a general rule, he used up four or five grains of cocaine daily in the form of a 5 per cent. solution, although occasionally as much as eight grains were used in a day. The cocaine was always applied with a long nasal brush, the spray never being employed, and the mucous membrane of the nose was the only part to which the application was made. He informed me that at first the use of the cocaine produced some sleeplessness, but that this passed away after employing it for two or three months, and that he drifted into the use of the drug on account of the feeling of freedom from worry and the local and general pleasurable sensations excited by it. The drug exerted no influence upon the sexual functions. During the latter half of the three years of its employment he had noticed a gradually increasing indisposition for work, together with a growing inaptitude for coming to a ready decision with regard to affairs connected with his business and daily life; also a disposition to shun society. He felt that his general health was not so good as formerly, and he had been subject for the last two years to chronic constipation, together with occasional attacks of palpitation of the heart and slight dyspepsia. I pointed out to him the probable connexion of his symptoms with the long-continued employment of cocaine, and strongly advised him to break himself of the habit, ordering him at the same time a simple tonic and to employ abdominal massage with a four-pound cannon-ball for five minutes every morning in order to relieve the constipation. Six weeks later he informed me that he had entirely broken himself of the use of cocaine, although for the first week he suffered from great depression, and had a strong desire to return to it. He had entirely recovered from all his bad symptoms, his mental decision and powers of application to work being thoroughly restored.

Westbourne-terrace, W.

CASE OF HYDATID MOLE.

By JAMES OLIVER, M.D., F.R.S. EDIN.

WELL-RECORDED cases of hydatid mole are sufficiently rare to warrant the publication of one which very recently came under my care at the Hospital for Women.

Annie T——, aged twenty-five, and married seven years, has had five full-time children and no miscarriage. The last child was born two years and four months ago. This child was suckled for sixteen months, and the patient was unwell each month during the first five months of nursing. After the child was five months old she was never again unwell until one month after weaning. The last child was the first which had been suckled by the mother. Menstruation was established at the age of fourteen, and it has usually lasted seven days. On April 22nd she began to lose, and continued to do so until July 10th, losing more or less every day—i.e., for eleven weeks. Prior to April 22nd she had not menstruated for three months, although until then, and after she had weaned the baby, she had been quite regular, and lost as usual. Besides complaining of constant hæmorrhagic discharge, she complained also of pain all over the lower part of the stomach. The pain came on generally at night, after going to bed, though it had occasionally been noted during the day. There was a constant feeling of "soreness of the stomach," such as one experiences after colicky pain. The patient began to lose blood before she complained of pain; the latter was remarked, however, within twenty-four hours after the establishment of hæmorrhage. For three weeks both lower extremities had been swollen, and pitted readily on pressure. Six weeks before she began to lose constantly there was noted a slight discharge of blood after coitus. There was no bladder or rectal trouble. Eleven weeks previously to my seeing the patient, she began to feel sick, and latterly she had actually vomited at least once every day. No movements had been felt. On examination, the abdomen was occupied by a uniformly globular swelling, located centrally, and reaching to one inch above the umbilicus. It was somewhat soft, but seemed to harden under the hand in consequence of contraction. No fœtal heart or uterine souffle could be detected. The swelling was tender all over to the touch. The breasts were not enlarged, but were, in fact, flabby, and no colostrum could be obtained from either. On vaginal examination, the cervix was soft and patent, and nothing was felt in the cervix itself. The abdominal tumour moved the cervix readily, and was uterine; it was equal in size to a six months' pregnancy. My diagnosis was pregnancy, the child being dead. On July 12th, two days after the patient saw me, I received a letter from Dr. Townsend of Lewisham High-road (whose patient Annie T—— was), saying: "A hydatid mole weighing 2 lb. came away this morning; there was a good deal of hæmorrhage, and I had to clean out the uterus, swabbing the cavity with perchloride of iron."

It is stated by the majority of authors that in cases of cystic disease of the ovum the tumour rapidly increases in size, and that the size does not correspond with the supposed period of pregnancy. In the above case there was no rapid increase, and the size of the tumour corresponded well with that of the supposed period of pregnancy—viz., six months. The discharge was always hæmorrhagic, and at no time had it been noted as watery.

Gordon-square, W.C.

WOUND OF THE RADIAL ARTERY.

By E. ST. GEORGE QUEELY,
GOVERNMENT MEDICAL OFFICER, MAYTOWN DISTRICT, AND SURGEON TO THE PALMER HOSPITAL, QUEENSLAND.

THE following case of wounded radial artery came under my notice lately, and is, I think, worthy of note from the length of time that elapsed before the patient was treated, and from the quantity of blood lost.

W. F——, a miner, aged twenty-eight, while working in a shaft of an Anglo-Saxon gold-mine, received a cut across the left wrist, occasioned by a fall of sharp quartz. The wound was about two inches long, extending from the base of the thumb upwards and inwards. There was considerable hæmorrhage for some time, but it was controlled, and after three days the man was able to be about, with his arm in a sling. On the fifth day hæmorrhage set in again, and the patient lost a large quantity of blood; but a poultice of salt eventually stopped it. From the great loss of blood he naturally became very weak and anxious, especially as on the twelfth day a loss of blood again took place. I was therefore sent for, and arrived on the fifteenth day after the accident. The distance I was obliged to travel being forty miles over very rough country, I did not reach him until late at night, and as he was comfortable and no hæmorrhage had taken place for fifteen hours, I thought it better not to do anything until daylight. Next morning I visited the camp and learned the man had slept well and felt better. On removing the dressing, I found the wound looking healthy and commencing to granulate. As there had been no sign of blood for twenty-six hours, I merely applied lint saturated with carbolic oil, and told his friends to use it three or four times a day. I also improvised a tourniquet with a piece of cork,

Digitized by Google

and marked a place over the brachial artery, with instructions to apply it immediately in case of any fresh discharge, and that as soon as he could sit on a horse he was to come into town, the food obtained where he lodged not being sufficiently nourishing. I visited the case four times during the day, but was obliged to leave for town, having several hospital patients to see. Three days afterwards I heard that hæmorrhage had set in worse than ever and could not be controlled, and that the patient had to be carried into the hospital in a dying state. He arrived seventy-two hours afterwards, and when admitted was in a very low condition and quite blanched. His forearm was greatly swollen from several tight ligatures having been tied tightly round his arm. I had him placed on the operating table and administered chloroform. He inhaled a large quantity before coming under its influence. All ligatures, bandages, &c., being removed, blood immediately spirted from the wound, but was as quickly stopped by the tourniquet. I found the lower end of the artery easily, and twisted it, but could see no sign of its upper end; so I made an incision upwards and inwards over the artery for about two inches, and at last was able to place a ligature round it. The wound was closed by three catgut stitches and a pad of lint put over it. The man recovered from the anæsthetic quickly, but suffered some pain, which was relieved next day by the subcutaneous injection of morphia. His diet consisted of strong essences, milk, eggs, and port wine, with ammonia and iron as a tonic. Twelve days afterwards the ligature came away, and the patient was discharged on the thirtieth day, cured.

Now the question in this case is, Should I have operated on my visit at first, or was I justified in my treatment? Some people (lay, of course) thought I should have done so immediately on my arrival; but as there was no sign of hæmorrhage, and none had taken place for twenty-six hours, I hold that I was right.

Queensland.

ON THE MECHANICAL TREATMENT OF AMENORRHŒA.

By ALEXANDER DUKE, F.K.Q.C.P.I.,
EX-ASSISTANT MASTER OF THE ROTUNDA HOSPITAL, AND GYNÆCOLOGIST AT STEEVENS'S HOSPITAL, DUBLIN.

THE mechanical treatment of amenorrhœa by the introduction of an intra-uterine stem to be worn for some time is frequently followed by the desired result. The danger, however, of uterine stems compels the practitioner to enforce the recumbent position on the patient; and as this becomes exceedingly irksome, more especially in the case of younger patients, sufficient time is seldom allowed to effect the looked-for result. An uterine stem to be worn with comfort should be flexible, hollow, freely movable, and require no vaginal support in addition. It should also permit of the patient going about as usual, the exercise contributing in no small degree to the action of the stem. The making of such a stem self-retaining has been the great difficulty met with, as the various modifications of the instrument will testify. With regard to the advantages of the galvanic stem, I have strong doubts as to its action. I have given it a trial on several occasions, and am fully persuaded that a foreign body of *any kind* introduced into the uterine cavity will act quite as well. The stem I recommend is formed of spiral wire (plated), which I originally designed for the purpose of keeping the os and cervical canal patulous after the operation of division of the cervix for stenosis, and it has given me every satisfaction. These stems are sold by Messrs. Arnold of West Smithfield, and are made in various sizes, so that if a proper size be chosen and introduced, the patient can go about as usual, and be quite unconscious of wearing such. Indeed, on one occasion I introduced one of my stems without the patient's knowledge, and was rewarded by the menstrual flow being established, which had been in abeyance for over a year. It must be distinctly understood that I do not advocate the indiscriminate use of the stem as a routine treatment for amenorrhœa, but only in those cases where the usual plans of treatment by medicine &c. have failed, and where the symptoms complained of are such as fully to warrant mechanical interference. The stem should be introduced to its full length, and I have found that the spring introducer lately designed by me is the best instrument for placing the stem *in situ*. The base of the stem being flat and very light, the vaginal walls embrace it closely and in such a manner as effectually to prevent its falling out. Having experienced the value of this treatment of amenorrhœa, I have confidence in recommending it to others.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

WEST LONDON HOSPITAL.

FIVE RECENT CASES ILLUSTRATIVE OF CEREBRAL SURGERY; REMARKS.

(Under the care of Mr. C. B. KEETLEY and Drs. DONALD HOOD, J. B. BALL, and COLMAN.)

(*Continued from page 542.*)

IN our issue for last week we gave the first case of the series, one in which the skull was trephined for a bullet wound of the brain, and in which, although only a partial removal of the bullet was effected at the operation, the patient recovered. We also gave the reasons for regarding the flow of pus which came from the wound three or four days after the operation in Case 2 as having its origin in a cerebral abscess. A method of preserving the crown of bone removed by the trephine for re-implantation is illustrated in two cases. In Case 3 operation was only resorted to as a last resource, and not with any great hope of success. There being a clear history of injury and of discharge from the left ear, it was thought justifiable to perform an exploratory operation.

CASE 2. *Cerebral abscess, (?) of traumatic origin; trephining; recovery.*—E. W——, aged fifteen, domestic servant, was under the care of Dr. W. S. Colman and Mr. Keetley. The present illness was said to date from three weeks before admission. She received a severe thrashing from her mistress, including three boxes on the left ear. She says that soon after, and not before, she had discharge from that ear, and pain over the left temple, fixed and persistent. She vomited for the first time four days ago. Appetite has been fair. Occasional squint, and also short-sightedness, were noticed on the left side before the blows were inflicted.

On admission the girl was anæmic, sallow, and looking ill. Pupils equal and natural. No twitchings anywhere. Increasing weakness and disinclination for exertion complained of. Fixed pain in left temporal region of a fortnight's duration. Earache has been present, but has gone off. Curious stoop when walking; no incoördination; walks in a straight line and stands steady, with her heels together. Forehead narrow, but alike on both sides. No tenderness on percussing any part of skull or compressing the mastoid processes. Some tenderness on pressing the left eye back, and there is slight proptosis. No twitchings or tinglings. Reflexes everywhere normal. Mind and memory unimpaired. No enlarged cervical glands. Chest narrow, otherwise normal. Vomiting till four days ago, not since. Temperature on admission 99·4°, pulse 80, respiration 32. The ophthalmoscopic appearances were—Left eye: myopia (4 D at least). Disc, cup gone; edge rather indistinct; rest of fundus natural. Right: disc much swollen, greyish and striated; vessels dip slightly at periphery; a little distance to the temporal side is a distinct hæmorrhage, and along the vessel to the nasal side is some white exudation. No tubercles seen in either eye. Vision quite acute; the field does not seem contracted in either eye. Colour sense normal. Hearing on the right side good, twenty inches; left side, only eight inches. No discharge from ear now. Mr. Wainewright reports perforation of tympanic membrane just behind the handle of the malleus. Bone conduction seems perfect on both sides. Smell and taste normal. No defect of function found in any of the other cranial nerves, though careful and particular search was made. Urine pale and

Digitized by Google

clear; sp. gr. 1012; excess of phosphates; no albumen or sugar.

With regard to the family history, the father is said to have sciatica and a weak chest; paternal aunt, "consumption and tumours." Paternal grandmother died of cancer. No important diseases on the mother's side. Is one of eight children; four dead ("fits," "whooping-cough," "diarrhœa," "wasting in six weeks"). The patient had whooping-cough badly when two years old. Well since, but has been getting weak for four months. Has been in a heavy "place" for nine months.

On April 11th and 12th the patient was each day minutely examined by Dr. Colman. The pain was being relieved by an ice-bag, but the optic neuritis in the left eye was rapidly increasing. The edge of the disc was distinguishable now only at the upper part. The vessels were buried in it for some distance, especially the lateral ones. Neuritis of the right eye not much increased. On the 11th she had a good night after a chloral and bromide draught.

The operation was performed by Mr. Keetley. The head was previously shaved, cleansed with soap, &c., and dressed for some hours with moist antiseptic gauze. Chloroform was given, and a semicircular flap turned down to expose the area about an inch and a half above, and one inch in front of external auditory meatus. The temporal fascia and muscle and pericranium were reflected sufficiently, and a medium-sized trephine used. Dura mater dull and tense, pulsating less than normally. This was punctured, and there was an escape of clear fluid, showing under the microscope red blood-corpuscles, but no pus. The dura mater was freely incised, some clear fluid escaping rather copiously. The exposed brain looked healthy and did not bulge. A fine trocar and cannula was then passed successively—(1) downwards and inwards until it impinged on the upper surface of the petrous part of the temporal bone (a dry base of a skull was held by an assistant in such a way that it was quite easy to calculate, with it in view, the exact path of the trocar); (2) backwards, downwards, and inwards into the posterior part of the temporo-sphenoidal lobe; (3) forwards, downwards, and inwards into the anterior part of the same; (4) upwards and forwards into the frontal lobe; (5) directly inwards. The results were negative. Nos. 2, 3, and 4 punctures were made to the full depth possible with the trocar, which was, unfortunately, only about two inches and a half long, the instrument which should have been used having been found rusted. The dura mater was stitched with two catgut sutures. Bone removed by trephine was broken up with bone forceps and replaced. Temporal muscle sewn with buried sutures, skin with silver. Dressing: iodoform crystals, iodoform gauze (moist), and sponge. Bandage and strapping (Leslie's) freely used. Pulse good throughout the operation, the duration of which was one hour. The patient was delirious two hours after the operation, but became quiet after a hypodermic injection of morphia. At 8 P.M. she began to vomit, and continued to do so every ten minutes. The bandage was taken off, and reapplied very loosely.

April 13th (10 A.M.).—Temperature 102°; pulse 100, regular. She rambles a great deal, and complains much of pain in the temple and in the left eye. Wound dressed; looks healthy. No facial or ocular paralysis, but amblyopia. Can now distinguish only figures (not faces). Much more comfortable after dressing, and more rational.

14th.—She has not vomited since 9 A.M. yesterday. Rather more pain at site of operation; also in occiput and over mastoid. Considerable mastoid tenderness and some fulness this morning. Temperature 100·8°; pulse 104, regular. On ophthalmoscopic examination the left disc was much paler than before the operation, and the vessels not so much embedded. Right eye: neuritis not much increased; cup still absent and edge blurred; vessels appear to dip slightly; no hæmorrhages. No tubercles in either eye.

15th.—Very good night. Appetite better. Some puffiness of left cheek and lower eyelid. Less tenderness of eyeball. Does not complain at all. Pulse 92°; respiration 22; temperature 99°.

16th.—Same as yesterday, but puffiness and tenderness less. No tenderness of left orbit now. Pus observed at the edge of the dressing. Wound dressed at 8 P.M.; a considerable quantity of pus in the dressing. Flap looks quite healthy. Silver sutures removed and cicatrix opened at each end. Much pus welled up, evidently from the trephine hole. Wound dressed as before. Microscopically the pus-cells were extremely granular, and there was a great deal of granular débris. On ophthalmoscopic examination the neuritis was much less in the left eye. Right eye almost normal. Temperature (evening) 99·2°. Bowels open five times.

18th.—From this date no rise of temperature occurred, excepting once on the 20th, when 99·6° was reached. No pain. No tenderness anywhere. Appetite good.

19th.—Manner a little strange. "Ringing in ears." Wound dressed; looking well; no puffiness. Slept soundly.

20th.—Ophthalmoscopic examination: Left eye, disc normal. Vision perfect.

May 2nd.—Since the last note she has continued perfectly well. The wound has been dressed once a week. There is not much discharge. On ophthalmoscopic examination the optic neuritis on the right side was not subsiding. Edge of disc still blurred; vessels rather more blurred than before. A torch-shaped hæmorrhage just beyond the temporal edge of the disc.

She remained in hospital three months and a half longer. On May 11th she complained of the sight of the left eye, which was myopic. The last ophthalmic note taken while she stayed in hospital was by Mr. Vernon on May 17th, when the right disc was hyperæmic; veins turgid, with irregular outlines, and disturbance of choroidal pigment. Left disc very much the same; not so hyperæmic; showed a myopic crescent upwards. Granulations at one or two points of the wound had several times to be cauterised. Frequently there were complaints of headache. On June 4th the note was: "Has been complaining of pain in left side of head as when she came in, and tenderness for the last two days. Slight discharge from left ear again to-day." On July 6th she "complained of tenderness and occasional pain in two spots, one just above the ear, and the other about two inches higher; otherwise well." On Aug. 9th it was noted that there had been pain every day in the neighbourhood of the wound, a little above it. There was aching of the left eye, the sight of which had not improved. The pain did not keep her awake at night or cause her much inconvenience. Left ear discharging. A dark-coloured, hardish concretion was washed out on the previous day. It was syringed daily. On the 17th there had been no more discharge from the ear. She complained of loss of memory. This was possibly due to inattention or carelessness, as interesting facts were well recalled, and the patient was able to repeat poetry learnt the day before. The pain over the wound and at another point a little behind it was not severe, but constant. The left eye was perfectly blind. On the 21st, her memory being better and the pain less, she was discharged. She has since occasionally attended the hospital, and was last seen recently, more than a year after the operation, looking and feeling quite well, without any pain, and with good sight in both eyes.

CASE 3. *Doubtful symptoms of intra-cranial suppuration associated with a history of injury and afterwards with discharge from the left ear; exploratory trephining; death; disease of pons Varolii (new growth?).*—M. P——, aged seven years, was admitted into Hull ward, under the care of Dr. Hood, on May 25th, 1888. Fourteen days before admission she had a fall while playing and knocked her head against a window-sill. A small bruise (just visible) appeared at the centre of the left superciliary ridge. She seemed at the time not much hurt, but rather stunned; there was no bleeding from the nose or ears. The next day but one after the accident she was observed to stagger in her gait and complained of giddiness, but there was no vomiting until the day before admission. The staggering had been getting worse until then, and she had a slight squint (had had none previously). Her appetite was as usual. The bowels were acting. She vomited only after food. She was said never to have had any discharge from either ear. Family history good.

On admission there was slight internal squint of the left eye. No headache. Pain in chest. The left eye moved well when the right was closed. Double vision. No optic neuritis. Knee-jerks distinctly exaggerated. No ankle clonus; no paralysis, either motor or sensory, in face or extremities. Watch heard at two feet from either ear, and also on contact with either side of the head. No tender spot anywhere. She was given confection of senna.

May 28th.—No material change. Had only vomited once. Squint more marked. Suspicion of ankle-clonus. Pain across temples. Gait still staggering. Diplopia present.

29th.—The patient was ordered to take castor oil, also one grain of grey powder three times a day. She vomited twice in the evening.

Digitized by Google

31st.—Woke up with a start three times in the night; her arms twitched each time.

June 5th.—Comfortable. No convulsion; no headache. Vomited at times after taking the powders.

11th.—A discharge from the left ear was noticed last night. Gait decidedly worse. Legs carried wide apart, and very tottering.

12th.—Much worse. Had vomited constantly since yesterday. Very little food kept down for the last three days. Had a restless night. At 6 A.M., after being washed, she became faint, cold, almost pulseless, and of a livid colour. This passed off soon. An ice-bag was applied to her head, and hot bottles to her body. She had pain over the left eye. Since then she had been drowsy, but understood what was said to her. She had vomited frequently. The squint of the left eye remained; the eyes were otherwise normal. Pulse 104, weak. Temperature subnormal. It was thought justifiable to perform an exploratory operation. A semicircular incision, with the convexity upwards, was made over the squamous part of the left temporal bone, and the skin, with the muscle and fascia, divided and turned downwards. The pericranium being reflected, a button of bone was removed with the trephine (crown the size of a shilling). This button was passed through a small incision previously made (antiseptically) in the skin of the left thigh, and lodged in the subcutaneous tissue until wanted again for replantation. A carbolised sponge and bandage held it in place. When the skull was opened, the dura mater bulged slightly and pulsated plainly. A small opening being made in it and two bleeding vessels secured, the left temporo-sphenoidal and frontal lobes of the brain were punctured by an aspirator needle and also by a director in different directions, but with negative results. The dura mater was sewn up again, the button of bone taken from the thigh was cut up into small pieces and laid over the dura mater, and the temporal muscle and fascia brought over all and sutured with catgut. Lastly, the skin edges were united (not tightly) with two silver sutures, and the wound dressed with moist iodoform gauze and sponge (for pressure). At 7 P.M. she was semi-conscious; nodded when questioned; and there was less squint. At 12 P.M. she had vomited once; she was still slightly conscious; the temperature was normal, and the pulse 96.

13th.—Had passed a restless night, throwing off the bedclothes. She had vomited once since midnight—i.e., twice since the operation; but she had kept down half-a-pint of milk this morning. She had passed urine and a motion while in bed. She became more conscious at 4 A.M. She could then lift her head when asked to do so, but was still very drowsy. Squint as before. Pulse 100; temperature subnormal.

14th.—Slept little, lying almost unconscious, occasionally asking for ice or milk. Had three attacks of faintness, becoming pulseless and cold for two minutes or so each time. Vomited four times since last evening. Restless, throwing her arms about and her head from side to side. Thirsty. Temperature normal; pulse about 140. At 3 30 P.M. she was quite insensible; conjunctivæ and corneæ insensitive (the pupils had been dilated with atropine for ophthalmoscopic examination). Limbs rigid, especially the *left* arm; slight ptosis of the right upper eyelid. Squint variable. Temperature 101°; pulse weak, and not easily counted, about 130 (?); respiration rapid. A little later the right arm became completely paralysed; the left a shade less (?). It fell less heavily when raised. The left fingers were more bent on the palm than the right. At 8.20 P.M. she vomited about half a pint of black fluid matter, and died immediately afterwards. Temperature 105·6° at 7 P.M.; 105° after death.

Necropsy.—"No inflammation on cerebral side of wound. No abscess discovered. Pons Varolii enlarged to about three times its natural size, uniformly of yellowish colour, both externally and on section. No other abnormality discovered. Brain kept by pathologist for examination." No further report has been received by Mr. Keetley.

PRESBYTERIAN HOSPITAL, CHICAGO.

HYDATID CYST OF THE ABDOMEN; OPERATION; RECOVERY.

(Under the care of the late Professor MOSES GUNN.)

WE have this year given examples of the successful treatment of hydatid cysts by the operation of direct incision and drainage after suturing of the cyst wall to the abdominal parietes.[1] We give below the account of a case in which it was attempted to secure adhesion of the apposed surfaces before incision of the cyst, but in which the method employed did not answer, and the operation, practically, was the same as that mentioned. Various other methods have been tried with the object of obtaining adhesion of the apposed surfaces before incision of the cyst wall. Barwell[2] recommended suturing of the abdominal wall to the cyst three or four days before the completion of the operation; Simon of Heidelberg tried multiple punctures with this object, but this method does not obtain much popularity. Baudeleben in the Congress of German Surgeons brought a series of successful cases treated by the application of Vienna paste to the abdominal wall over the cyst. It required some six or seven days for the caustic to act, and the process was a painful one. Ranking made an incision through the parietes and then removed two semilunar pieces of the abdominal wall, incising the cyst at a later date. In this case the cyst appears to have resembled an enlargement of the pancreas in its early stages. For the following account we are indebted to Dr. C. W. Ward, who was the house surgeon during this patient's residence.

Charles W—— was admitted about June 5th, 1887. He was thirty-three years of age, married, a blacksmith by trade, and active in his habits. He was born in Germany, and the elicited family history was very good. Seven years ago, then a resident of Germany, the patient was seized with a sudden attack of abdominal pain, and a medical man, on palpation of the abdomen, found the existence of a tumour, and a diagnosis of hypertrophied pancreas was made. With this tumour there existed more or less ascites and marked abdominal distension. Fourteen weeks of diuretic treatment removed the ascitic condition, and the patient again resumed his vocation, feeling no appreciable discomfort, save a slight mental anxiety at the continued presence of the tumour. It caused no inconvenience until six years later, when he suffered from a second, though less severe, attack of pain, from which he seems to have quickly recovered.

On admission an examination was made. The subjective symptoms were a sharp cutting pain referred to the seat of the tumour, and a troublesome fermentative distension of the viscera following the ingestion of food. The objective symptom was a tumour located two inches and a half to the left of the mesial line and an inch or so below the hypochondrium. The protruding abdomen conveyed an impression of its size to be about that of a small orange. The tumour was scarcely movable, elastic and tense to the touch, and caused no pain or tenderness when manipulated. On percussion, an area of dulness existed corresponding in size to that of the tumour. The characteristic thrill known as "hydatid fremitus" which is observed in large hydatid cysts filled with daughter cysts, and which is probably produced by the concussion of these with each other, was here elicited, and upon that sign a diagnosis of hydatid cyst was pronounced. His complexion was sallow, appetite good, bowels regular, and urine normal.

The patient was advised to submit to an operation, but as he had known of a "similar case in Germany" that resulted fatally, his courage failed him, and he declined, leaving for home that night. However, a month later (July 8th) he returned, having in the meantime laid the matter before his family and his friends, who induced him to reverse his decision and accept operative measures. There had been no alteration of symptoms during this time, and Tuesday, July 12th, was arranged for making the primary incision.

The operation was planned to consist of two steps: the first, to cut down upon the tumour until reaching the internal fascia of the rectus abdominis muscle, then pack the incision with iodoform gauze, aiming thereby to excite inflammatory adhesion of the peritoneum; the second, then to open the cyst cavity, evacuate its contents so far as possible, and resort to drainage for what might remain. As occasionally occurs, so here, the plans were only partially realised. The incision was made over the tumour in the left hypochondriac region about four inches in length, and the wound well packed with iodoform gauze.

One week later (July 19th) the packing was removed, but no evidence of adhesion was found. Nevertheless, the fascia was opened and the cyst wall exposed. The cyst wall, which was recognised by its greyish, cartilaginous, and translucent appearance, was opened on the grooved

Digitized by Google

director, and the contained fluid, limpid and serous in character, jetted forth. On enlarging the opening, the daughter cysts, opal-like bodies, came forth in great profusion. By means of a large hæmostatic forceps, often used in colpo-hysterectomy for controlling hæmorrhage from the ovarian arteries, many daughter cysts were removed. The incised cyst wall was then sutured to the abdominal walls by six silk sutures, and a drainage-tube half an inch in diameter introduced into the cyst to a depth of about six inches. The cyst was then thoroughly cleansed with a 5 per cent. solution of carbolic acid, dressings applied, and the patient placed in bed. The 6 P.M. record showed the temperature to be 100·4°; pulse 102.

July 20th.—Passed a quiet night, but failed to sleep. Maximum record: temperature 99·4°; pulse 98. He received a small amount of nourishment, such as milk, tea, toast, and egg. Urine 28 oz. Dressings saturated every twelve hours with 2 per cent. carbolic acid solution.

21st.—Patient slept well during the night. Breakfast consisted of beefsteak, oatmeal, coffee, and toast. At 7.10 A.M. the temperature was 100·8°, and the pulse 104; at 1.45 P.M., temperature 101·6°, pulse 112; 8.30 P.M., temperature 103°, pulse 102. At 2 P.M. the dressings were changed and quite a number of daughter cysts were "fished out" by the use of the hæmostatic forceps. Many of them presented a biliary colouring, thus showing their proximity to the liver. At 9 P.M. the patient was given twenty grains of antipyrin.

22nd.—Slept well till 3 A.M. Felt sick and refused breakfast. At 10 A.M. he was given two drachms of sulphate of magnesia, and at 3 P.M. ten grains of antipyrin. At 8.15 A.M., temperature 100·2°, pulse 98; at 2 P.M., temperature 101·4°, pulse 100. At 3 P.M. the dressings were changed; more "fishing."

In a week the patient walked about the ward. The wound was dressed daily, carbolic acid (5 per cent. solution) being used for irrigation. At each dressing resort was made to the "fishing" process.

Aug. 26th.—The last daughter cyst was removed to-day. Dressings changed each alternate day, and the use of the drainage-tube still continued. Appetite good and general health unimpaired. Walks about the lawn.

Oct. 1st.—The drainage-tube has been lessened and shortened, but not yet discarded. Complains of a "nervousness" that worries him. Boric acid irrigations substituted. Ten minims of dilute phosphoric acid given three times a day as medicine. Out-door exercise advised.

Nov. 22nd.—Drainage-tube removed. "Nervousness" continues.

Jan. 16th.—Patient discharged. Abdominal opening merely a fistula. Discharge simply serous and small in amount. Still "nervous."

On May 15th Dr. Charles W. Hall wrote: "W—— walked into my office with a firm step. He enjoys excellent health and is in good spirits. His only complaint is that of weakness or unsteadiness in his legs, and that after five days of labour he is so tired as to feel it necessary to rest the other two days of the week. The cicatrix is prominent, and contains a fistulous opening about the size of a small quill, which discharges slightly."

Remarks by Dr. WARD.—Two months later I saw the patient, and found him about as described above. In closing I want to inquire, What caused the "nervousness" of which he continually complained?

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Polypus of the Gum.—Brain Tumour with Thinning of Skull.—Melanotic Sarcoma of the Eye.—A Fœtus with Cystic Kidneys.

A MEETING of the Pathological Section was held on May 31st.

Mr. ARTHUR W. W. BAKER read a paper on the subject of Polypus of the Gum. These tumours vary from the size of a pea to a horse chestnut, and are found on the gum in the neighbourhood of diseased teeth. They are said to be chiefly caused by the ragged edge of a carious tooth, but it is probable that the ptomaines resulting from the operations of the bacteria in the dentinal tubules have more to do with their etiology than is usually supposed. Wedl and Rothman, in their writings, support this view. The growths in question are essentially papillomatous, and exhibit on section large branching papillæ covered with a thicker layer than normal of squamous epithelium. The polypi are purely local in their origin, and non-malignant.—Dr. SCOTT said that the growths were papillomata. These growths were an advanced link of connexion between papilloma and epithelioma, between which there was a well-known clinical difference.—Dr. CHARLES BALL said the tumours were an example of the way in which irritating discharges produced papillomatous and sometimes even adenomatous growths.—Mr. BAKER, in reply, said he was glad that Dr. Scott looked on them as a connecting link between papillomata and epitheliomata, for that was his (Mr. Baker's) own view with respect to them, although he could not say that the slides showed sufficient evidence of it.

Dr. BALL showed a Tumour of the Brain (angio-sarcoma) as large as a turkey's egg, occupying the right occipital and portion of the temporo-sphenoidal lobes. The symptoms during life were pain in the head, vomiting, double optic neuritis, and the presence of a pulsating venous tumour on the vertex, from which large veins radiated, and beneath which a perforation of the skull could be felt. The case was diagnosed as one of perforating angioma, probably originating in the dura mater; and, acting on this diagnosis, simultaneous ligature of both external carotid arteries above the origin of the facial was had recourse to, with a view of diminishing the blood-supply through the middle meningeal and temporal arteries. All symptoms were relieved for a month, after which they reappeared, gradually increased in severity, and proved fatal, the patient remaining conscious and free from all paralysis to the last. The necropsy showed that the venous tumour of the vertex was caused by a number of veins coming through the skull and carrying the blood from the great longitudinal sinus, the normal flow of blood into the right lateral sinus being prevented by the pressure of the tumour on the torcular Herophili, at which place it was adherent to the dura mater—a condition similar to the caput medusæ met with at the umbilicus in cases of obstructed vena cava. The inner surface of the skull was roughened and eroded over its entire extent. He considered that the marked improvement following operation for a short time could only be accounted for by the loss of blood at the operation, and subsequently by a moderate secondary hæmorrhage relieving the intra-cranial tension.—Dr. PATTERSON said the tumour was very sharply differentiated from the surrounding brain substance, and its outer surface was covered with a dense network of vessels, suggesting extreme vascularity. As to the etiology of the tumour, he thought it highly probable that it originated in the perivascular sheaths, and developed from them, for in some places the vessels could be seen surrounded by rings of sarcomatous tissue. As to the little nodules removed from the dura mater, they also seemed to be sarcomatous tissue. It was right to state that this system of starving tumours by cutting off the vascular supply had not hitherto been attended with very satisfactory results, even in cases where the vessels dealt with directly communicated with the tumour.—Dr. BENNETT said he was equally responsible with Dr. Ball for the error of diagnosis. The condition of the cranium was due to an increase of intra-cranial pressure—not a local, but a general increase, such as occurred in hydrocephalus in children.—Mr. SWANZY said that with a tumour in the right occipital lobe there should have been hemianopsia on the right side. That could hardly have been missed, and it would have pointed to a lesion very far from the position in which the only lesion was supposed to be.—Dr. MILES said that lesions of the occipital lobe were associated with colour-blindness. It was very difficult to conceive how a large tumour like this could have existed without giving rise to paralytic symptoms. In fact, as far as they could see, the presence of a pulsating tumour of the scalp appeared to have overridden everything else in the diagnosis.—Dr. BALL, in reply, said the first question was as to whether there had been erosion of the inside of this skull or not. As to this, a great deal depended on what was meant by erosion. That the surface of the bone had been absorbed in many places there was no doubt; and the inner surface of the external plate had become exposed.

Dr. E. H. BENNETT exhibited an example of Melanotic Sarcoma of the Eye remarkable for its slow growth, while

Digitized by Google

its histological characters were eminently malignant. The disease had been detected as intra-ocular more than eight years ago at St. Mark's Hospital. Some considerable time since the globe had given way, and a fungus protruded, which had attained the size of a closed fist. Of late this fungus bled freely; this symptom at last frightened the patient—a woman nearly fifty years of age—and caused her to submit to its removal. The removal was facilitated by the fact that under ether the muscles no longer supported the fungus, and its sac (the remains of the globe) was exposed by the tumour falling out on the face. The bleeding, which was very free, was at once arrested on the removal of the globe. On section the tumour was seen to be formed of a jet-black mass, except in part, where a lobe of white tissue strongly contrasted with the remainder. Microscopically, the tissue appeared in many parts that of alveolar sarcoma.

Dr. BAGOT showed a Female Fœtus with Congenital Cystic Degeneration of the Kidneys. Externally, with the exception of the enlargement of the abdomen, the child presented no malformation. On opening the abdomen, he found that it contained about two ounces of peritoneal fluid. The peritoneum covering the kidneys was thickened, and showed signs of inflammation, band-like adhesions passing to the intestines. The latter were in some places adherent to each other. The ureters were extremely thin, but pervious. Both kidneys were symmetrically enlarged; but cysts were nowhere visible on their surfaces. On section their normal structure was seen to be replaced by an extremely fine network of minute cysts, thus resembling the variety of kidney described by Virchow as "the fine cystoid." The tubules could be seen to have undergone an irregular dilatation, some appearing normal, others more or less dilated, till in most parts they had become replaced by large epithelial-lined spaces. The epithelium of the tubules appeared in many places to have undergone proliferation—a condition which was also present in some of the glomeruli. The bloodvessels were greatly congested, and hæmorrhages into the tissues could be seen here and there. Concerning the etiology of this condition various theories have been put forward, amongst which that by Virchow has been the most generally accepted—viz., that it is caused by atresia of the papillæ, due to a fœtal inflammation, brought about by an abundant deposit of urinary salts in the tubules. Thorn, however, believes that this condition is more frequently brought about by inflammation passing from the calices to the substance of the papillæ; while Chotinsky says that occlusion of the tubules is to a great extent due to successive multiplication of the epithelium. Others hold that it is due to a primary fault of development, and that in this condition "we have really to do with a more or less persistent mesonephros, associated in greater or less degree with normal renal tissue.

Lectures on General Pathology. By JULIUS COHNHEIM. Translated from the Second German Edition by ALEX. B. MCKEE, M.B. Dub. Section 1: The Pathology of the Circulation. London: The New Sydenham Society. 1889.

THE publication of the work wherein the late Professor Cohnheim may be said to have gathered the harvest of his remarkable scientific career is an event regarding which the New Sydenham Society deserves great credit. It has, indeed, often been a matter of surprise to us that no English translation of these "Vorlesungen" should hitherto have appeared, for they in no small measure mark an epoch in the history of pathology. The first edition appeared in 1877, and the second in 1882. Two years later, at the early age of forty-five, their gifted author passed away, leaving behind him not only this but numerous other contributions to pathology which bear the stamp of genius. In a sense, indeed, Cohnheim created a new school of pathology in his aims at studying it from the experimental and physiological side; and, brief as was his career, he succeeded in not only adding new and important contributions himself, but in inspiring many workers to pursue investigations of many problems upon new lines and methods, with far-reaching result. It may be that in the more recent pursuit of the etiology of morbid processes, in the absorbing and fascinating study of the relations between bacterial organisms and disease, there has been a diversion of attention from the important subjects with which Cohnheim mainly dealt. But when the history of pathology comes to be written there cannot fail to be found a most prominent place for such work as he did, both in the facts he disclosed and the fertile suggestions that he made, especially in such subjects as embolism, inflammation, anæmia, tuberculosis, and morbid growths.

The volume before us contains that section of the lectures which deal with the Circulation. It embodies, therefore, much of the ground with which the author himself was personally most familiar. Opening with the study of the circulatory derangements depending upon lesions of the heart and its valves, and passing thence to the conditions of the circulation in the peripheral vessels, the subjects of local Anæmia and Hyperæmia are fully discussed. Next the author deals with Thrombosis and Embolism, where we note the statement of the view that thrombosis occurs not in consequence merely of the arrest or stagnation of the blood stream, but on account of the impaired nutrition of the endothelial lining of the vessels which such stagnation may itself occasion. It is shown also that in the "organisation" of a thrombus it is not essential even for the vessel wall to participate, but that the whole process may be effected by emigrant wandering cells penetrating the thrombus from without, for of course the older idea of direct conversion of the clot is quite abandoned. The results of the softening of thrombi and the mechanical effects of thrombosis upon the circulation lead naturally to a discussion of the subject of embolism, which is dealt with in an exhaustive and most interesting manner. Many readers will doubtless turn to the following chapter, that on Inflammation, in the expectation of finding it treated in a philosophical manner: nor will they be disappointed; for whether we regard the style in which the description of the process is given, the minute and painstaking way in which each of its phenomena is treated, or the completeness with which the whole subject is viewed on all sides, this chapter by itself bears the impress of the master hand. The subject of inflammation is in truth the keystone of morbid action, and it was Cohnheim's great service to demonstrate the preponderant influence of the circulation in the process. The remaining topics dealt with in this volume, Hæmorrhage and Anæmia (we would draw special attention to the discussion of "essential anæmia"), although each of them of great interest, pale in importance before this unique exposition of inflammation.

The influence of Cohnheim's teaching has shown itself in many recent works on pathology, but hitherto the English-reading student has had to be content with the descriptions of his work at second-hand. He will now have the opportunity of studying the words of the teacher himself, and he cannot fail to be impressed by the depth of knowledge and clear thinking that are evinced on every page. For this boon he has to thank the New Sydenham Society, and especially the able translator, Dr. McKee, who has succeeded admirably in the by no means easy task of rendering such a work as this into another language without impairing the freshness or terseness of the original.

The Anatomy of Labour, as studied in Frozen Sections, and its bearing on Clinical Work. By A. H. F. BARBOUR, M.D. Edinburgh: W. & A. K. Johnston. 1889.

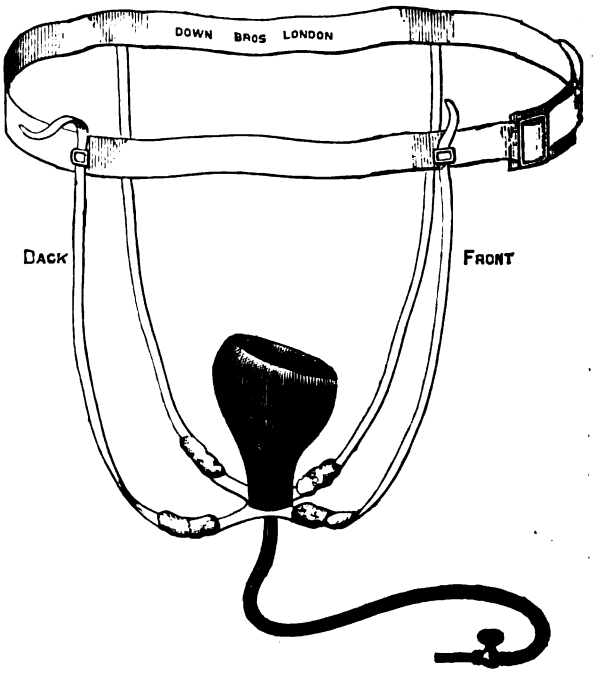
THIS little book is explanatory of the author's Atlas on the same subject. Though small in size, it is great in

Digitized by Google

value, summing up as it does the present condition of knowledge on the subject, for much of which we are indebted to Dr. Barbour. The first part of the book gives these results; the second gives the literature of the subject in the form of references, tables, and summaries. The amount of work, of one kind and another, here represented is very great, and the book will always, we think, maintain its place as a standard authority on the anatomy of labour. The uterus and pelvis are treated before labour, in each of the stages of labour, and after labour. The facts are derived from gross and from microscopical evidence, and include the consideration of the "lower uterine segment," which, though not yet fully worked out, seems to belong unmistakably to the body, and not to the neck of the womb.

There are few criticisms for us to make. A few changes might be made in a subsequent edition, which would make some details clearer. For instance, on page 46, the placental site is described as thicker, and on page 52 as thinner, than the rest of the uterus. In Chapter 4 the word "conjugate" is incorrectly used (*passim*) to denote antero-posterior diameters other than that of the brim. A "conjugate" is a technical term, meaning the lesser diameter of an ellipse, and only applies to the antero-posterior diameter of the brim. There is an advantage in this, inasmuch as it is only necessary to speak of the "conjugate," since the only conjugate is that of the brim; and it is as unnecessary and redundant to speak of the "conjugate of the brim" as it would be to speak of the brain of the head or the fingers of the hand. It is plain that, in future, the terms "extension" and "flexion" can only be taken to denote the lesser or greater coincidence of the long axis of the head with that of the genital canal, and not separation or approach of the chin from or to the chest. The elevation of the pelvic peritoneum, except that of Douglas's pouch, during pregnancy, and still more during labour; the relation of the ureters as regards the possibility of their compression; and the imperfect elevation of the bladder during labour, are all of great interest. In Chapter 5 the bearing of clinical facts on frozen sections of the third stage is considered. Here we think a little more caution was required, for, as regards the clinical facts, some of the most important of them have been the subject of prolonged discussion and reinvestigation, with the result that former descriptions require revision. There is no trace of this in the chapter before us, and, while the literature of frozen sections is given, the literature of the clinical side is not alluded to. For many reasons, the evidence of frozen sections from the third stage of labour is less weighty than that of the other stages, and the question is not yet settled. It is not unlikely that some of the statements here made will have to be withdrawn, and we hold that in a work like the present this should never be necessary. It is far better to assert nothing which cannot be proved, for unproved assertions often cost others much weary and unnecessary trouble, and really impede the advance of knowledge.

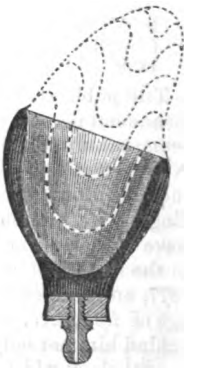
The book, small as it is, is so full of facts that it is not easy to find what is searched for, especially as the object of search often occupies pages remote from each other. An index, and a pretty full one, should certainly be added. A second edition of this excellent work should be even more valuable.



VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea.—On the 11th inst., the Organising Committee and delegates from the temperance trades and friendly societies and clubs handed over to the chairman and committee of the hospital the sum of £272 16*s.* 10*d.*, being the net proceeds of the most successful church parade which has yet been held in Chelsea.

New Inventions.

HYDROSTATIC REPOSITOR.



CASES of chronic inversion of the uterus are happily not of very frequent occurrence, but they are sufficiently common to warrant the adoption of special means in their treatment. No amount of manual dexterity and patience, however great, will suffice to replace the chronically inverted uterus, but steady and well-directed mechanical pressure will generally effect reduction. The cup and stem repositors, which have hitherto been used with much success, are open to at least two objections: 1. The necessity for changing the cups as reduction proceeds. 2. The difficulty in withdrawing the instrument when reduction has been

FIG. 1.

effected; for not only does the cervix then grip the stem *below* the cusp, but this latter also acts as the plunger in a suction pump, and the negative pressure induced by attempted withdrawal is very great. The report in THE LANCET of May 18th of cases related at a meeting of the Obstetrical Society of London fully illustrates these difficulties. I have therefore been induced to elaborate the rough model of a hydrostatic repositor which I designed in the year 1886. The instrument was exhibited at the Leeds meeting by the makers, Messrs. Down Bros. It consists of a double india-rubber bag (Figs. 1 and 2) mounted on a steel X-shaped frame, and connected with a stout rubber tube called the supply-pipe. It is kept in position by four *in*elastic perineal bands attached to the four points of the X frame and buckling on to a stout waistband, which latter may, if required, be coated with adhesive plaster. The arrangement of the frame leaves the meatus urinarius and the anus uncovered, so that the patient is enabled to micturate and defecate. The pressure is applied through the supply-pipe by any fluid, from compressed air to mercury (oil alone excepted), and by any means, from a Higginson's syringe to a reservoir over the patient's bed, or the ordinary service supply-pipe. Its advantages are:—1. It can be thoroughly disinfected by any solu-

FIG. 2.

Digitized by Google

tion (e.g., sublimate) before use. 2. The bag being elastic, it envelops the womb; and the power being hydrostatic, it adjusts itself accurately to that organ, while the pressure is uniformly distributed over the whole of the body to be reduced. Thus the bloodvessels and lymphatics are emptied, engorgement is diminished, and reduction materially favoured. 3. The pressure being constant and uniform, reduction takes place in the line of least resistance, and the receding uterus is steadily followed up by the reducing agent. 4. The posterior border being longer than the anterior, the axis of the curves of reposition tends to coincide with the axis of the uterus. (Fig. 2.) 5. The pressure can be regulated to a nicety, especially by a reservoir suspended over the patient's bed. 6. Reduction may be effected with the patient in any position, from the genu-pectoral to the dorsal decubitus. 7. Reduction having been effected, the bag is emptied by disconnecting the supply-tube and the reservoir. The upper part then collapses, and the whole is easily withdrawn from the vagina.

Fig. 1 represents the repositor with the bands and belt attached. Fig. 2 is semi-diagrammatic, the shaded portion representing a vertical section through the inverted cup (ready for use), and the dotted lines, approximately, the various curves assumed during distension of the instrument and reposition of the uterus. The instrument has been well and faithfully made from my detailed drawings by Messrs. Down Bros. of St. Thomas's-street, Borough.

B. CAMPBELL GOWAN, M.R.C.S., L.R.C.P., L.S.A.
Great Stanmore.

THE BRITISH ASSOCIATION.

THE various Sections of the British Association commenced their labours on Thursday, the 12th inst., large audiences being the rule and the addresses being well received.

BIOLOGY SECTION.

Canon Tristram read the address which had been prepared on this subject by the President of the Section, Dr. Burdon Sanderson, who was prevented by illness from being present. After an introduction the address proceeded:—

"Physiology first studies man and the higher animals, and proceeds to the higher plants, then to invertebrates and cryptogams, ending where development begins. From the beginning her aim has been to correlate function with structure, at first roughly, afterwards, when her methods of observation became scientific, more and more accurately, the principle being that every appreciable difference of structure corresponds to a difference of function; and, inversely, that each endowment of a living organ must be explained, if explained at all, as springing from its structure. It is not difficult to see whither this method must eventually lead us. For, inasmuch as function is more complicated than structure, the result of proceeding, as physiology normally does, from structure to function must inevitably be to bring us face to face with functional differences which have no structural difference to explain them. By multiplying examples, they would in each case come to this issue—plurality of function with unity of structure, the unity being represented by a simple structural element, be it retinal cone or cell, possessed of numerous endowments. Whenever this point is arrived at in any investigation structure must for the moment cease to be our guide, and in general two courses or alternatives are open to us: one is to fall back on that worn-out *Deus ex machinâ*, protoplasm, as if it afforded a sufficient explanation of everything which cannot be explained otherwise, and accordingly to defer the consideration of the functions which have no demonstrable connexion with structure as for the present beyond the scope of investigation; the other is, retaining our hold of the fundamental principle of correlation, to take the problem in reverse—i.e., to use analysis of function as a guide to the ultra-microscopical analysis of structure. I need scarcely say that of these two courses the first is wrong, the second right, for in following it we still hold to the fundamental principle that living material acts by virtue of its structure, provided that we allow the term structure to be used in a sense which carries it beyond the limits of anatomical investigation—i.e., beyond the knowledge which can be attained either by the scalpel or the microscope. We thus proceed from function to structure, instead of the other way. In thus changing direction we are not departing from the traditions of our science."

Having dwelt upon the discoveries of Haller and others, the address went on to describe life as "a cyclosis in which the organism returned after every cycle to the same point of departure, ever changing, yet ever the same." After touching upon the relation of oxygen to living matter and vital process and other cognate subjects, an outline or sketch was given of what might, if there were time to complete it, be an adequate conception of the mechanism and process of life. The following passages concluded the address:—

"What we have to guard against is the mixing of two methods, and, so far as we are concerned, the intrusion into our subject of philosophical speculation. Let us willingly and with our hearts do homage to 'divine philosophy,' but let that homage be rendered outside the limits of our science. Let us, if we are so inclined, cross the frontier and philosophise; but for my part, as a physiologist, I feel more disposed to do my best to furnish professed philosophers with such facts relating to structure and mechanism as may serve them as aids in the investigation of those deeper problems which concern man's relations to the past, the present, and the unknown future."

ANTHROPOLOGICAL SECTION: HEREDITY.

The President, Sir William Turner, F.R.S., delivered an address upon "Heredity." After some introductory observations, Sir W. Turner said that in its relations to man, his structure, functions, and diseases, the subject of heredity had long occupied a prominent position in the minds of anatomists, physiologists, and physicians. That certain diseases, for example, were hereditary was recognised by Hippocrates, who stated generally that hereditary diseases were difficult to remove, and the influence which the hereditary transmission of disease exercised upon the duration of life was the subject of a chapter in numerous works on practical medicine, and formed an important element in the valuation of lives for life insurance. Sir W. Turner described at some length the latest discoveries in the field of biology, and referred extensively to Charles Darwin, Mr. Francis Galton, Professor Weismann, and others. The lecturer then proceeded to examples of hereditary malformation, and continued as follows:—"These examples illustrate what may be called the coarser kinds of hereditary deformity, where the redundancies or defects in parts of the body are so gross as at once to attract attention. But modifications or variations in structure that can be transmitted from parent to offspring are by no means limited to changes which can be detected by the naked eye. They are sometimes so minute as to be determined rather by the modifications which they occasion in the function of the organ than by the ready recognition of structural variations. One of the most interesting of these is the affection known as Daltonism, or colour-blindness, which has distinctly been shown to be hereditary, and which is due, apparently, in the majority of cases, to a defect in the development of the retina, or of the nerve of sight which ends in it, though in some instances it may be occasioned by defective development of the brain itself. Dr. Horner has related a most interesting family history, in which the colour-blindness was traced through seven generations. In this family the males were the persons affected, though the peculiarity was transmitted through the females, who themselves remained unaffected. The family tree showed that in the sixth generation seven mothers had children. Their sons, collectively nine in number, were all colour-blind with the exception of one son, while none of their nine daughters showed the hereditary defect. ..... The eye is not the only organ of sense which exhibits a tendency to the production of hereditary congenital defects. The ear is similarly affected; and intimately associated with congenital deafness is an inability to speak articulately, which occasions the condition termed deaf-mutism. ..... Mr. David Buxton, who has paid great attention to this subject, states that the probability of congenital deafness in the offspring is nearly seven times greater when both parents are deaf than when only one is so; in the latter case, the chance of a child being born deaf is less than ¾ per cent.; in the former, the chances are that 5 per cent. of the children will be deaf-mutes. ..... Had one been discussing the subject of hereditary disease twenty years ago, the first example probably that would have been adduced would have been tuberculosis, but the additions to our knowledge of late years throw some doubt

Digitized by Google

upon its hereditary character. There can, of course, be no question that tubercular disease propagates itself in numerous families from generation to generation, and that such families show a special susceptibility or tendency to this disease in one or other of its forms. But while fully admitting the predisposition to it which exists in certain families, there is reason to think that the structural disease itself is not hereditarily transmitted, but that it is directly excited in each individual in whom it appears by a process of external infection due to the action of the tubercle bacillus. Still, if the disease itself be not inherited, a particular temperament which renders the constitution liable to be attacked by it is capable of hereditary transmission.....The germ from the cancerous parent must be so far different from the normal as after the lapse of years to engender the cancerous condition. Heredity is also one of the most powerful factors in the production of those affections which we call gout and rheumatism."

After adducing several family histories in which the heredity of cataract and other diseases is suggested, Sir W. Turner went on to treat of the transmission of acquired characteristics, and said:—

"If we could conceive both parents to be physiologically perfect, then it may be presumed that the offspring would be so also. ..... Should both parents be physiologically imperfect, we may expect the imperfections, if they are of a like nature, to be intensified in the children. It is in this respect, therefore, that the risk of consanguineous marriages arises, for no family can lay claim to physiological perfection. ..... So far as man is concerned, the evidence in favour of a tendency to the transmission of both structural and functional modifications which are either of disservice or positively injurious, or both, is quite as capable of proof as that for the transmission of characters which are likely to be of service. Hence useless as well as useful characters may be selected and transmitted hereditarily. I have dwelt somewhat at length on the transmissibility of useless characters, for it is an aspect of the subject which more especially presents itself to the notice of the pathologist and physician, and little, if at all, to that of those naturalists whose studies are almost exclusively directed to the examination of organisms in their normal condition. But when we look at man, his diseases form so large a factor in his life that they and the effects which they produce cannot be ignored in the study of his nature."

Having pointed out the conflict of opinion existing as to whether the somatogenic acquired characters are transmissible from parent to offspring, Sir William Turner continued:—

"It may appear, therefore, to be both rash and presumptuous on my part to offer an opinion on this subject. I should, indeed, have been slow to do so had I not thought that there were some aspects of the question which seemed not to have been sufficiently considered in its discussion. In the first place, I would, however, express my agreement with much that has been said by Professor Weismann on the want of sufficient evidence to justify the statement that a mutilation which has affected a parent can be transmitted to the offspring. It is, I suppose, within the range of knowledge of most of us that children born of parents who have lost an eye, an arm, or a leg come into the world with the full complement of eyes and limbs. The mutilation of the parent has not affected the offspring; and one would, indeed, scarcely expect to find that such gross visible losses of parts as take place when a limb is removed by an accident or a surgical operation should be repeated in the offspring. But a similar remark is also applicable to such minor mutilations as scars, of the transmission of which to the offspring, though it has been stoutly contended for by some, yet seems not to be supported by sufficiently definite instances. I should search for illustrations of the transmission of somatogenic characters in the more subtle processes which affect living organisms, rather than those which are produced by violence and accident."

In conclusion Sir William Turner said:—

"Man is a living organism, with a physical structure which discharges a variety of functions, and both structure and functions correspond in many respects, though with characteristic differences, with those which are found in animals. The study of his physical frame cannot therefore be separated from that of other living organisms, and the processes which take place in the one must also be investigated in the other. Hence we require, in the special consideration of the physical framework of man, to give due weight to those general features of structure and functions which he shares in common with other living organisms. But, whatever may have been the origin of his frame, whether by evolution from some animal form or otherwise, we can scarcely expect it ever to attain any greater perfection than it at present possesses. The physical aspect of the question, although of vast importance and interest, yet by no means covers the whole ground of man's nature, for in him we recognise the presence of an element beyond and above his animal framework. Man is also endowed with a spiritual nature. He possesses a conscious responsibility which enables him to control his animal nature, to exercise a discriminating power over his actions, and which places him on a far higher and altogether different platform than that occupied by the beasts which perish. The kind of evolution which we are to hope and strive for in him is the perfecting of this spiritual nature, so that the standard of the whole human race may be elevated and brought into more harmonious relation with that which is holy and divine.'

Mr. Francis Galton, F.R.S., read a paper on the "Advisability of assigning Marks for Bodily Efficiency in the Examinations of Candidates for the Public Services," and pointed out that the proposal had no reference whatever to the pass examinations now made by medical men in order to eliminate candidates who are absolutely unfit, but to give additional marks to those youths who, being fit for service, were at the same time exceptionally well fit so far as bodily efficiency was concerned.

Papers were also read by Dr. J. G. Garson (in the absence of Dr. Ridolfo Livi) on the "Development of the Wisdom Teeth"; by Dr. W. K. Sibley, on "Left-leggedness," which went to prove that, whilst man was naturally or artificially right-handed, he was at the same time left-legged; and a paper on the subject of "The occasional Eighth True Rib in Man and its relation to Right-handedness," by Professor D. J. Cunningham. The proceedings then closed.

CHEMISTRY SECTION.

Amongst the papers read in this Section was one by Dr. ISAAC ASHE, entitled "Dimidium: an attempt to represent the Chemical Elements by Physical Forms, with Models of the Elements, from Hydrogen to Nickel, constructed in accordance therewith." The author pointed out that when the combining weight of an element was divided by the number representing its combining power, or valency, as compared in both cases with hydrogen, the quotient in many cases presented the fraction ½, instead of an integer number; and that in many other cases, particularly in the triad series, an integer quotient, with unity for a remainder, was to be obtained by doubling the combining weight before dividing. Hence he inferred that an element having half the weight of hydrogen would be found to be the primordial element out of which the other elements were constructed. This hypothetic element he proposed to call "dimidium." The number of atoms of dimidium which would go to form any given element would be double the number representing the combining weight of that element as compared with hydrogen. Dimidium itself might probably consist of a number of vortex rings, according to Sir W. Thomson's theory, placed one on the top of another, thus forming an elongated circular bar; a limit would be placed to the length of the bar so compacted, in consequence of a point being reached on each side of the centre, in a lengthwise direction, where the forces of attraction and repulsion between the rings balanced each other. Possibly the hollow tube thus formed might itself be filled with some still lower form of matter, out of which the vortex rings themselves might have been made, perhaps perfect spheres, to which Mr. Crookes' term "protyle" might be applied. Assuming, then, the existence of this primordial linear element, and representing its atoms by small metallic bars of brass wire, the author showed that—taking in each case the number of bars indicated as above, by doubling the combining weight of each element—he had been able to construct a series of models of the chemical elements, in which their combining power, their positive or negative condition, and their modes of combination were all expressed, as well as their combining weight. He further showed that the forms brought out in these models corresponded with the crystalline forms known to belong to certain of these elements; and how the phenomenon of the expansion of water when freezing might be explained by reference to the form employed for the

Digitized by Google

molecule of that compound, which was hexagonal in its general outline. The forms adopted for the elements in these models were also shown to correspond with the arrangement of the elements in series by Newlands and Mendeljeeff, elements belonging to the same series having corresponding forms. The author suggested that simple geometrical forms—that is to say, the equilateral triangle and the square—were the combinations into which the primordial element would first have entered, and all the models were accordingly constructed out of these forms, along with the simple bar. Thus the atom of hydrogen was constructed of two single bars placed side by side, and the molecule of four, and he suggested that these were probably separated in the gaseous condition so as to form a hollow cube. There were other secondary forms constructed out of the triangles and squares, and the models of many of the elements were then constructed out of these secondary forms. Lithium was formed of two squares and two triangles, or fourteen pieces, its combining weight being 7. Carbon was formed by placing two pyramids base to base, each pyramid being formed of four equilateral triangles, in all twenty-four pieces, its combining number being 12. The crystalline forms, both of the diamond and of graphite, were shown to correspond with this, the former being made by placing a number of the carbon atoms together by their edges, and the latter by placing them in apposition by their triangular facets. The author suggested that probably metals combined with non-metals by lateral interpenetration, a salient angle of the former corresponding with a re-entrant angle of the latter; but that two non-metals combined by superposition, corresponding angles being applied one to the other. The union of boron with nitrogen at a high temperature was shown by reference to the models to be an illustration of this view. The compounds of oxygen with nitrogen and with chlorine were also discussed, and a corresponding explanation of them suggested. What is known as the nascent condition of elementary atoms was explained as consisting in a sliding movement between two atoms which had been combined, so that one of these was removed gradually from the other, while a third gradually replaced it by a similar sliding movement, the atom so removed necessarily entering into combination with a fourth.

THE AMINES PROCESS OF SEWAGE PURIFICATION.

A LARGE company of gentlemen, in response to the invitation of Mr. E. B. Ellice-Clark, M.I.C.E., assembled on Wednesday last at the Wimbledon Sewage Farm to inspect the method of purification of sewage, now being carried out there, and known as the Amines process. Amongst those present were the Lord Mayor, several members of the Main Drainage Committee of the London County Council, as well as many well-known civil engineers, chemists, medical officers of health, and others interested in sanitary matters. "No known process of precipitation purifies sufficiently," was the conclusion the late Royal Commission came to in 1884. Yet the elaborator of this process of precipitation, Mr. Wollheim, claims for it not only a clear effluent, but one absolutely free from all organisms and sterile. The actual process differs little in its working from other precipitation processes, so that it can easily be put in operation without much outlay at sewage works where such methods have been in use.

The pure sewage is pumped up, and by suitable contrivance definite quantities of milk of lime and herring brine are added to it. It is then allowed to flow over an agitator into settling tanks. Clarification rapidly takes place, and is usually complete in half an hour. The clear effluent, smelling of brine, is then run off, and more sewage, with a smaller proportion of lime and brine, is run in on top of the residual sludge. This process is repeated six or more times. The sludge is then allowed to gravitate into the filter press house, where it is pressed into "cake." Samples we took from the press possessed only a slight ammoniacal smell. In his address Mr. Ellice-Clark stated that the sludge, containing 90 per cent. moisture, may be thrown on the land without giving rise to any nuisance, even under conditions of weather most favourable to putrefaction. No claim was urged having regard to the practical use or value of the sludge.

Dr. Klein has examined (by inoculation on nutrient gelatine) both the sludge and the effluent. In the former he reports finding fewer organisms than are found in filtered river water supplied by the London companies, and in the latter absolutely no organisms at all. And, further, that when the effluent is diluted with water containing organisms actual decrease in the number takes place rather than increase. This disinfecting and antiseptic property of the material employed is assigned by the inventor to a gaseous reagent soluble in water, and evolved by the action of the milk of lime upon the herring brine, to which he has given the name "Aminol." As to cost, Mr. Wollheim states that it may be given in round numbers as ranging from a halfpenny to three farthings per thousand gallons of sewage treated, and in the case of London sewage, taking the daily flow at 130,000,000 gallons, the cost need not exceed £330 daily, equal to about £125,000 per annum, which means 7½*d.* per head of the population, or a rate below 1*d.* in the pound. Most of those present on Wednesday seemed to think favourably of the process. The local board of Wimbledon expressed their satisfaction with this treatment, which has been carried out now at their farm for the past two months.

We failed to detect anything of an objectionable character in or around the premises; and the process, apart from the novelty of its active agent, from which is derived its name, deserves to enlist the interest of all concerned in sanitary science.

THE HYDERABAD CHLOROFORM COMMISSION.

To the Editors of THE LANCET.

SIRS,—I am directed by his Highness the Nizam's Government to offer THE LANCET, as the leading medical journal, £1000 to send out a representative to repeat the experiments of the Hyderabad Chloroform Commission, and make any others with the Commission that you may suggest.

1. The Hyderabad Committee performed a series of experiments, of a clinical nature, on the effects of chloroform in dogs in 1888, and their conclusions were embodied in a report which was submitted to Government early this year.

2. The experiments of the Commission tend to prove that chloroform has no direct action upon the heart, and though it is hardly to be expected that their conclusions will be accepted as final by the whole of the medical profession, their work may be safely said to constitute an interesting addition to what is already known about chloroform.

3. The Nizam's Government has been advised that if the experiments are continued and amplified by the Hyderabad Commission, associated with a trained scientist, whose position and attainments will ensure the acceptance of his opinions by the profession, the subject might be threshed out thoroughly, and the question whether chloroform does or does not affect the heart directly, and other questions connected with it, might be settled once for all.

4. His Highness's Government therefore desires to offer £1000, a cheque for which is forwarded herewith to the Editors of THE LANCET, to send a representative to Hyderabad to repeat and continue the experiments of the Hyderabad Chloroform Commission, and make with them any others that THE LANCET chooses to suggest.

5. If his Highness's offer is accepted, the gentleman selected should take a return ticket by P. and O. *vid* Brindisi for three months, to be extended if necessary, and he will be the guest of the Nizam's Government during his stay in Hyderabad.

6. The Hyderabad Commission undertake to place themselves entirely at his disposal and will act under his direction. The Commission will provide all instruments and appliances and everything which may be required for the experiments, and will, without bias, do all in their power to assist the representative of THE LANCET in arriving at the truth.

I have the honour to be, Sirs,

Your most obedient servant,

EDWARD LAWRIE,

Hyderabad, Aug. 18th, 1889. Surgeon-Major, Residency Surgeon.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 21, 1889.

AT the meeting of the British Association at Newcastle, just concluded, two addresses on biological subjects were delivered, one by Professor BURDON SANDERSON, the other by Professor TURNER, which claim a passing notice. It was much to be regretted that Professor BURDON SANDERSON was, in consequence of severe indisposition, unable to attend the meeting and deliver his own address. This duty in his unavoidable absence was undertaken by the Rev. Canon TRISTRAM. The theme on which Professor SANDERSON dilated was the Nature of Life, or, perhaps, to speak more correctly, the difficulties which at present stand in the way of giving any satisfactory explanation of the intimate nature of the vital processes and the quarter from which aid may be anticipated. The determination of the chemical and physical endowments of living matter in general, and of the several varieties of living matter which constitute the animal and plant organism, is, he pointed out, the first duty of the physiologist in particular. He must then ascertain how these processes are localised so as to constitute the special function of each structure and the relation between structure and process in each case. There can be little doubt that we must look to chemistry for the next steps in physiological inquiry. We owe an immense debt to the microscope, which has supplied information of extreme interest in regard to all the various organs of the body. But it is not by this means that we shall gain an insight into the nature of the intimate processes of nutrition, of the contractility of muscle, or of the excitability of nerve. Function, as Professor SANDERSON remarks, is more complicated than structure, and the result of proceeding, as physiologists commonly do, from structure to function must inevitably be to bring us face to face with functional differences which have no structural difference to explain them. In every instance the ultimate issue proves to be plurality of function with unity of structure, the unity being represented by a simple structural element, be it retinal cone or cell possessed of numerous endowments. The problems that may be regarded as most urgently demanding solution are those which relate to the endowments of apparently structureless living matter, and the problem of the future will be the analysis of these endowments. In order that it may be worked out, those cases should be selected in which the vital process offers itself in the simplest form, and is consequently most easy to understand, and then, following the fundamental principle of the correlation of structure with function, of mechanism with action, we may proceed to draw inferences as to the mechanism by which these vital processes are actually carried out. After further showing that living differed from non-living matter in undergoing constant change whilst remaining the same, Professor SANDERSON observed that it was this antithesis which constitutes the essential distinction between the two great branches of biology. Seen from the morphological side, the whole plant and animal kingdom constitutes the unfolding of a structural plan which was once latent in a form of living material of great apparent simplicity. From the physiological side this apparently simple material is seen to be capable of the discharge of functions of great complexity, and therefore must possess corresponding complexity of mechanism. It is the nature of this invisible mechanism that physiology thirsts to know. Each step in general science affords further and further insight into the nature of vital processes, and demonstrates that they are not essentially different from those with which we are already familiar. The chemical investigations of BLACK and CAVENDISH and LAVOISIER, for example, led to clear conceptions of the changes involved in respiration; the cell theory founded on the researches of SCHLEIDEN and SCHWANN and VIRCHOW gave an insight into the deeper processes of nutrition, which has been greatly extended by the modern conception of protoplasm; but we are still far from understanding the essential difference between a living and a non-living body, though Professor SANDERSON believes that such knowledge is approachable.

In selecting Heredity for the subject of his address to the Anthropological Section, Professor TURNER interested not only the small number of his hearers who are specially engaged in investigating the history of man, but a far larger audience who are interested in the observation and treatment of his diseases, as well as those who are engaged in the breeding and rearing of animals. Though the ancient doctrine, that the seed of the animal or plant contains the adult in miniature, has been dismissed, and we no longer believe that the spermatozoa are homunculi, a doctrine almost as incredible is now very generally accepted to the effect that the germ plasm is transmitted, with all its original forms and potentialities, from parent to child, and has been so transmitted for an indefinite period—in fact, since the origin of the human race. The cells possessing these extraordinary powers are, as a rule, separated from the rest of the cells of the body at an early period of its development. They take no part in the growth of the organism in which they arise, and the principal reason for their association with other cells of the body is that certain of the latter minister to their nutrition. For the production of a new animal or plant, it is necessary that a process of fusion should take place between two particles named respectively the male and female pronucleus; and this fusion has been demonstrated in very humble members of both kingdoms. As the new individual grows, the germ plasm again separates from the rest, bearing, as it were, the torch of life to the next generation. Each new individual is, however, endowed with the power or faculty of variability, enabling it to adapt itself, within certain limits, to the conditions by which it is surrounded, and these adaptations, if favourable to the life of the individual, are capable of hereditary transmission, and may then, in course of time, lead to the formation of new species; if unfavourable, they lead to its degeneration or extinction. Professor TURNER demonstrates that in some instances structural lesions are transmitted—such, for example, as defect of digits, hare-lip, colour-blindness, and deaf-mutism; whilst in others there is inherited a strong predisposition to disease, as is seen in cancer, tubercle, hæmophilia, and cataract. The structural changes which there is every reason to believe exist in the

Digitized by Google

germ plasm, and lead to structural defect or to particular tendencies and susceptibilities, are too recondite and delicate to permit of their being recognised; but it is not improbable that much light might be thrown upon this point by well-directed and carefully performed experiments upon the fertilised ova of the lower animals. It is still held by some physiologists that acquired characters cannot be transmitted from parent to offspring; but if this supposition were correct, it would follow, as Sir WILLIAM TURNER observes, that the primordial human germ plasm must have contained within itself an extraordinary potentiality of development—a potentiality so varied that all the multiform variations in physical structure, tendency to disease, temperament, and other characters and dispositions which have been exhibited by all the varieties and races of men who either now inhabit or at any period of the world's history have inhabited the earth must be included in it; and, still further, if it be true that all living beings have descended from a single cellular organism, this must have contained in its molecular constitution the potentiality of evolution into higher and more complex forms of life, a doctrine that requires much faith to accept. And there seems good reason for accepting Sir WILLIAM TURNER'S conclusion that somatogenic characters are transmitted and form an important factor in the production of hereditary characters.

IT will not be amiss to draw a few lessons from the prosecutions which have been so ably and successfully conducted at Birmingham against the quacks that infest that town. Birmingham would appear to have more than her share of such characters; but it can scarcely be supposed that she differs much in this respect from other towns where the same diseases and, alas! the same ignorance prevail. Venereal disease is too constant everywhere. Everywhere is the same dread of its consequences, affording a lucrative source of profit to the charlatan. Equally ubiquitous is the disposition to have it treated secretly and to believe anything in either the threats or the promises of the most audacious pretenders. Such prosecutions as that reported last week ought to enable the sufferers and the public generally to see that there is one thing almost more to be feared than these diseases—viz., the men who trade on them, and on those who fancy they suffer from them, with perfect indifference to anything but the extortion of money. The great proof of wisdom in men in regard to these diseases is in avoiding them altogether, and all the risks and sources of them, as the worst form of pestilence, and one entirely preventable. But the next greatest proof of wisdom is, when the disease has been contracted or there is any reasonable fear that it has been, to go at once to the medical man best known and most respected. Of all indiscretions, that is the greatest which leads a man with this disease to consult such quacks as these prosecutions have brought to light, who were ready to pronounce perfectly healthy men who consulted them to be "very ill," and "to need months of treatment," and still more ready to extort from them exorbitant fees for their impudent opinions and their quack medicines. There is no ear into which the confession of error and its consequences can be more fitly made than that of the medical man. It is his business at once to receive such communications and to give such advice as will curtail the mischief that may have arisen, to abate undue fear, and to facilitate the return to health and self-respect. He is of all men the one who can make the most allowance at the same time that he most powerfully dissuades from evil courses. We cannot forbear to notice the fact, shown by the prosperity of these pretenders, that while the working classes expect medical practitioners to treat them for small and inadequate sums, they are always ready to pay large charges for quack medicines and to quack practitioners. The more bold and audacious the pretenders are, and the higher they appraise themselves and their medicines, the more easy does it seem for them to exact heavy fees from people who would be shocked by a general practitioner asking them half-a-crown or five shillings for advice.

It is worth while to notice a few of the legal points that cropped up in these cases. Dr. ROGERS had his case well in hand, and was ready with all points. He was clear in his own mind at least as to the legal grounds on which to base a claim for conviction, and at times most effective and humorous in his examination of witnesses. The defendants were charged generally with falsely holding themselves out as legally qualified practitioners in medicine and surgery. CHARLES FREDERIC GROOM, of 44, Great Charles-street, was charged specially with falsely using the title of a Member of the Royal College of Surgeons. Mr. TRIMMER was in court, and gave evidence that in October last he had communicated to GROOM the resolution of the College of Surgeons withdrawing his diploma on account of an objectionable pamphlet, and requiring him to return his diploma, which he had not done. Dr. ROGERS contended that no person was entitled to represent himself as legally qualified unless he was registered—as GROOM'S counsel admitted he was not. Dr. ROGERS quoted Baron POLLOCK as laying down that if even a properly qualified medical man took the title of "Doctor" without being legally entitled to do so he infringed the law, and argued that an unqualified man who took such a title must be a much greater sinner. Not only did GROOM call himself "surgeon" and "Dr. GROOM," but JOHN MARSTON, a carriage builder, called himself "Dr. HUNTER," and JESSE KEY called himself "Dr. CURTIS." KEY had been convicted thirteen years since for illegally practising. The defence was hollow throughout. Mr. VACHELL, on behalf of GROOM, asked how he was to know that he had been struck off, seeing the College met with closed doors, and it could not be proved that the communication announcing his being struck off the roll had reached him. On behalf of MARSTON, the coach builder, Mr. VACHELL alleged his possession of a Philadelphia degree, as if it were not notorious that the University of Philadelphia had been deprived of its charter for the disgraceful sale of all sorts of degrees. There was, in fact, no defence, and the stipendiary magistrate, Mr. HILL, convicted all three "for falsely using the title of 'Doctor.'" The magistrate granted a case on each conviction, but we have not much fear of any reversal of his decision.

We cannot leave these prosecutions without a word of praise for the Medical Defence Union, to whose energy and public spirit we owe the successful results. It is a matter for painful surprise that the public authorities of such an

Digitized by Google

enlightened municipality as Birmingham should allow such pestilential quackery to flourish in its midst, where there is law so easily available, if only the authorities would take a little trouble or empower the police to do so. It is disappointing that the College of Surgeons, which did so well in withdrawing GROOM'S diploma, did not follow up their action by prosecuting him for still using the title after being deprived of the membership on which it was based. It ought not to have been left to the Medical Defence Union to vindicate the sanctity of medical titles, and to prosecute the most pernicious of public and advertising quacks. The public and the medical corporations should combine to save the community from such pests and the profession from such disagreeable duties. Let us hope that a few such prosecutions, with all their disclosures of fraud and imposture, will stimulate them to do their duty. Meantime society owes a deep debt of gratitude to the Medical Defence Union, which, created for strictly medical defence purposes, has thus gone out of its way to do a great public service by exposing a great public evil.

ACUTE INFLAMMATION of the peritoneum arises under so many conditions that the study of its pathogeny would, it might be thought, be of especial value in determining the nature of the inflammatory process in general. One must welcome, then, any fresh contribution to the subject which, in view of its frequency and importance, has not perhaps been so thoroughly investigated as many far less valuable questions. Such a contribution is afforded in the current issue of *Virchow's Archiv* (Band 117, Heft 3) by Dr. PAWLOWSKY of St. Petersburg, who relates in detail a long series of experiments conducted by him in Professor ROSENBACH'S laboratory at Göttingen—experiments which go a considerable way to clear up many of the difficulties that surround this subject. It may be well, before adverting to his results, to follow him in his opening survey of the work hitherto done in this line of inquiry. He reminds us that in 1877 WEGNER published a series of researches upon the functions and action of the peritoneum, which were a distinct advance on the knowledge available up to that time, but the importance of which has been to some extent overlooked. WEGNER'S experiments largely consisted in noting the effects of the injection of air and of fluids of various kinds into the peritoneal cavity. He demonstrated that many such injections were quite innocuous, the material being rapidly absorbed without producing the slightest evidence of irritation of the serous membrane; and he also showed how rapidly peritoneal wounds healed. He found, too—and this before the real significance of pyogenic organisms was clearly understood,—that even in the case of fluids containing putrefactive bacteria the result depended apparently upon the amount of fluid injected, small quantities being absorbed without ill effects. At the same time he clearly conceived the notion that cases of rapidly fatal peritonitis, where death was often attributed to "shock," were really examples of general septic poisoning due to the absorptive powers of the peritoneal sac; and further believed that the fatal issue of acute suppurative peritonitis was owing to a similar blood-poisoning. There can now be no question that the reason for the immunity enjoyed by the peritoneum from the effects of certain of the fluids with which he experimented was due to the fact that they were devoid of any pathogenic organisms. GRAWITZ, who ten years later (1886) also made an experimental study of peritonitis, arrived at the conclusion that the serous membrane itself must be first injured or altered before general purulent inflammation could be excited by the injection of pyogenic organisms. WEGNER dwelt more upon the conditions of the peritoneum as a cavity into which fluid could be poured out, and from which it could be absorbed. GRAWITZ, on the other hand, directed especial attention to the wall of the cavity and its maintenance in a state of integrity. MIKULICZ, at the Berlin Surgical Congress in 1887, related experiments upon perforative peritonitis, and found that subsequent washing out the cavity with either carbolic or sublimate solutions was of no avail, whilst similar treatment with boracic or salicylic acids resulted in saving 50 per cent. of the animals in whom peritonitis had been so excited. But what was the nature of the poison derived from the intestine in such cases that had the power of exciting peritonitis, or why it was that carbolic acid and corrosive sublimate failed to arrest the process, were matters still left *sub judice*.

The question of experimental peritonitis had, then, reached this stage when PAWLOWSKY determined to carry it further. He planned a number of experiments to observe the effects of the action (1) of chemical agents, (2) of microbes, (3) of the intestinal contents, and (4) of combined chemical agents and microbes upon the peritoneum. The experiments were all conducted with strict observance of aseptic rules, and great care to avoid injury to viscera by the injecting syringe. The "chemical irritants" employed comprised croton oil, trypsin, and the products of two well-defined pathogenic organisms—staphylococcus aureus and streptococcus erysipelatis. One fact was clearly established—viz., that the infective forms of peritonitis were vastly favoured by the previous irritation of the membrane by chemical agents, thus confirming the proposition advanced by GRAWITZ. But the great merit of PAWLOWSKY'S work lies in the differentiation of the types of inflammation produced in these various ways. The peritonitis excited by the injection of the above-named chemical substances was invariably hæmorrhagic — never purulent; and side by side with this fact was the entire absence of microbes in the peritoneal exudation. Even in cases where the inflammation had been most severe, there was no lesion of the intestinal walls, no penetration of micro-organisms into the peritoneal cavity, no trace of suppuration. But when—as in some instances—the post-mortem examination was deferred beyond two hours after the death of the animal, then microbes could be detected in the peritoneal fluids, showing that (even before putrefaction had set in) these organisms could penetrate the dead but not the living tissues. The experiments with injections of cultures of micro-organisms fell under three series. In the first, non-pathogenic microbes were employed, without any result. Then the staphylococcus aureus, as the most typical and virulent of pyogenic organisms, was injected in varying quantities, and found to be highly provocative of peritonitis, even when administered in minute amounts. In the most severe cases death ensued within twenty-four hours, and the peritoneum showed hæmorrhagic and fibrinous exudation, with perhaps some admixture of

Digitized by Google

"catarrhal" cells, evidently indicative of commencing suppuration, which advanced to a greater degree the longer the animal survived. Experiments were also made with bacillus pyocyaneus, held by many to be non-pathogenic, and it was found to be almost as pyogenic as the staphylococcus. The conclusions from these experiments, which illustrated infection of the peritoneum from without, point to no less than four types of peritonitis being so induced: viz., (*a*) the mycotic form, the most severe and rapidly fatal, where the membrane is coated in places with a scanty mucoid exudation, consisting mainly of bacterial colonies; (*b*) hæmorrhagic exudation with more or less admixture of pus and microbes; (*c*) a fibrino-purulent form, obviously due to less intense infection, and marking the commencement of suppuration; and (*d*) typical purulent peritonitis, which is most markedly attained by the combined action of mechanical and chemical irritation, and the presence of pyogenic microbes in such amount as to produce comparatively slight general infection, and therefore to permit of the longer survival of the animal. Another series of experiments was concerned with the etiology of perforative peritonitis, and with this object injections into the cavity were made of filtered and unfiltered or diluted intestinal contents. The main results were that similar varieties could be produced by this mode of infection from within (i.e., intestine), as in infection from external sources, according to the amount and quality of the material introduced. Apparently microbes play an important part here also, but the precise micro-organism responsible for the inflammation in man has not been determined. In the rabbit, PAWLOWSKY isolated a bacillus from the intestinal contents, which was doubtless the cause of the peritonitis. It may be gathered, therefore, from his research that general acute peritonitis, which tends to become, or, owing to the survival of the microbe for a sufficient period, does become purulent, is invariably due to the presence of microbes which may be introduced into the cavity from sources external to the body, from the intestinal canal, or from some local source of infection elsewhere in the body. Also that the operation of these bacteria is favoured by associated irritation of mechanical or chemical nature, which *per se* induces hæmorrhagic but never purulent exudation.

PAWLOWSKY refers also to another interesting point in the history of acute peritonitis—viz., the frequent association with it of splenic tumefaction and of pleurisy. In explanation of these concomitants he reminds us that the peritoneum is a large lymph sac, and that its wall is furnished with stomata opening into the surrounding lymphatics; that there is thus an almost direct connexion between the pleura and the peritoneum, and also between the latter and the lymph space of the spleen, through its capsule; that a path of invasion of these parts by the peritonitic microbes is thus open; and that the presence of such microbes in the spleen leads to its reactive hyperplasia. As to the cause of the fatality of acute peritonitis, it is, on this microbic doctrine, due to general infection. If the virus be of small amount, it is conceivable for it to be absorbed into the thoracic duct, carried away in the circulation, destroyed and excreted as is the case with simple exudations; but if it be of greater amount or virulence the microbes will be found accumulating around the stomata, which they soon occlude, and then, multiplying in the peritoneum, produce purulent effusion, besides increasing the danger of general sepsis. The practical inference from such considerations is that *early* laparotomy is indicated in every case of infective peritonitis, but there yet remain points as to the etiology and treatment of the disease (especially that due to intestinal perforation) that await inquiry.

A SOMEWHAT important case, involving a question as to the proper interpretation of Section 126 of the Public Health Act (1875), came before the Malling Petty Sessions last week. The section imposes a penalty on exposure of infected persons and things, such penalty being incurred by any person who "gives, lends, sells, transmits, or exposes, without previous disinfection, any bedding, clothing, rags, or other things which have been exposed to infection"; and in pursuance of this provision the rural sanitary authority of Maidstone summoned a parent whose children were alleged, whilst affected with scarlet fever in its desquamative stage, to have been engaged in an orchard gathering currants which were subsequently transmitted to London. Mr. BUTTERFIELD was present as medical witness on behalf of the authority, but the details of the case were not gone into, on the ground, taken by the magistrates, that it was very doubtful whether fruit was so far *ejusdem generis* with the other articles named in the section as to be properly included in the term "other things." On behalf of the sanitary authority it was contended that this term included everything in the "wide, wide world" that could be shown to be capable of conveying the infection; but the magistrates evidently felt that, even with the aid of expert medical evidence, they could not undertake to decide whether fruit carries infection or not; and although they showed their sympathy with the sanitary authority by refusing to allow the defendant's costs and by stating that cases of this kind should be brought under the notice of the Legislature, yet they decided that they had no jurisdiction.

We imagine that there are conditions of fruit gathering which can leave but little doubt as to the danger of conveying particles of scarlatinal epithelium from fruit gatherer to fruit consumer, although it might be extremely difficult to prove, in an individual case, that any special parcel of fruit was actually thus infected, or was the actual cause of any case of scarlatina. But, in all probability, the magistrates may have been influenced in their decision as to the meaning of the term "other things" by the absence of any well-known cases in which fruit has conveyed infection, whilst the other articles named in the section are recognised carriers of the specific contagia. The point deserves to be carefully borne in mind by medical officers of health and others in cases of scarlatina or other diseases having an obscure origin. We only recall one instance in which the matter has come under any detailed investigation, and in the brief account of it given in the *Practitioner* (July, 1883) it is admitted that whilst "the employment as strawberry gatherers of persons in the desquamative stage of scarlet fever" came under suspicion, yet the case was complicated by the circumstance that those who consumed the strawberries and who subsequently contracted scarlatina had mixed the fruit with a cream which could not be exonerated from a share in the suspicion as to the source of the infection.

Annotations.

"Ne quid nimis."

"THE LANCET" AND THE HYDERABAD CHLOROFORM COMMISSION.

ON another page we print Surgeon-Major Lawrie's letter containing details of His Highness the Nizam of Hyderabad's offer to place at the disposal of THE LANCET, as the leading medical journal, the sum of £1000 to send out a representative to repeat the experiments of the Hyderabad Chloroform Commission, and to make any others that we may suggest. This offer we have cheerfully accepted. There are many young men of great ability and thorough scientific training who could have done this work exceedingly well, but in accordance with the Nizam's desire that we should select a man who is not only a trained scientist, but one whose position and attainments will ensure the acceptance of his opinions by the profession, we have requested Dr. Lauder Brunton, F.R.S, to act as our representative, and he has consented to set out for Hyderabad on Oct. 4th, which is the earliest possible opportunity. Dr. Lauder Brunton has not only devoted much time to pharmacological work for more than twenty years, his first contribution on the action of nitrite of amyl having appeared in our columns in 1867; but the fact that his large work on "Pharmacology and Therapeutics," which appears also in an American edition, has been translated into French, and is now being translated into German, Italian, and Spanish, shows that he is regarded as an authority in other countries as well as our own. It may perhaps be considered as a farther advantage that in this work Dr. Lauder Brunton has very decidedly stated that one of the dangers resulting from chloroform is death by stoppage of the heart. "Audi alteram partem" is the motto of an important section of THE LANCET; and we think that by getting both opinions regarding the effect of chloroform on the heart represented on the Commission, as they will be by Dr. Lauder Brunton and Surgeon-Major Lawrie, we are more likely to obtain a correct conclusion. The question whether chloroform paralyses the heart or not is one of the greatest possible practical importance, for upon its correct solution the lives of thousands of people and the happiness of thousands of families may depend. Both in Europe and America clinical experience and physiological experiments have led to the conclusion that it has a paralysing action on the heart, while ether exerts such an action in a very minor degree, if at all. In consequence of this, ether is now largely used in this country as well as in America for producing anæsthesia in surgical operations, in spite of the greater pleasantness and convenience of chloroform. It is almost impossible to believe that the conclusion at which European and American surgeons and scientists have arrived is, after all, destitute of foundation, and little better than an idle dream. When we find, then, that Dr. Lawrie and the Nizam's Commission have arrived at an entirely opposite conclusion, it is natural that we should hesitate to accept it. A consideration of the report of the Commission appears to show that the number of experiments performed was not only large, but the results were so uniform that the conclusion arrived at—viz., that chloroform does not paralyse the heart, but kills by stopping the respiration—may fairly be taken as correct for the animals experimented on, and for the conditions under which the experiments were performed. But if we grant this we are at once confronted by the next problem: Why do the results of the Nizam's Commission differ from those of European and American investigators? Is it because the experiments in India were carried on in a warmer climate? Or is it because the animals experimented on were peculiarly resistant to the action of chloroform? These questions can only be answered by further experiments, which can hardly fail to be of practical utility, even if they afford only a partial solution of the problem. For Surgeon-Major Lawrie states in his letter, which appeared in our issue of May 11th, that the results of the experiments carried out by the Commission tallied exactly with his own experience. In the correspondence which occurred on the subject in THE LANCET some writers agreed with Dr. Lawrie, while others supported the opposite view. We may perhaps fairly call these two views those of the Edinburgh and London schools. In the Scotch capital failure of respiration is regarded as the chief or only danger, while in the metropolis failure of the heart is more feared. It is quite possible that the surgeons in both cities are right, and that the habits or mode of living of the people may lead to differences in the resisting power of the cardiac or respiratory apparatus respectively. The proportion of gouty patients is much larger in London than in Edinburgh, and when we consider that the natives of India appear to resemble the Scotch in their comparative immunity from cardiac paralysis by chloroform, it will be advisable for the Commission to ascertain, if possible, what the conditions are which enable the heart either in dogs or men to resist the power of chloroform or which lead to its stoppage during the administration of the drug. It may not be possible to work out completely all the questions which may arise, but if the Hyderabad Commission, with the aid of Dr. Lauder Brunton, can settle definitely the question whether chloroform does or does not affect the heart directly, a most important practical object will have been attained by means of the Nizam's generous offer.

COMPETITIVE EXAMINATIONS.

AT the meeting of the British Association on the 12th inst. Mr. Francis Galton brought under the consideration of the Anthropological Section the important question of physical qualifications as an element in deciding the relative position of the candidates for appointments in the public service. It appears that some years ago a joint committee of the Civil Service Commissioners and War Office drew up a scheme of competition for admission to Woolwich and Sandhurst, in which the physique of the candidate received a fair amount of consideration. For some reason, which is not stated, this scheme was not brought into operation. Recently, the Commissioners appear to have again suggested the expediency of some such measure, but were informed that "the military authorities did not think it necessary to introduce such a competition, being completely satisfied with the physique of the young men who came to them through our examinations." We cannot but think that the military authorities—presumably the Commander-in-Chief and Adjutant-General—have committed a grave error in this decision. There can be no question that for service in the Army, the Navy, and the Indian Services a good physical development is, if not an absolute necessity, at least a great additional qualification for efficiency. It may be true that, under the present system, no deficiency in this respect has been experienced; but if so, this has probably been a result of the care exercised by the medical officers on whom the duty of inspection of the candidates has devolved. The importance of securing for these services men who are well qualified, physically as well as mentally, for the hard work which is often required of them, must be obvious, and it seems desirable from that point of view that a certain standard of fitness should be required, and that such qualities should be considered in judging of the relative fitness of the candidates. The result of a literary examination affords no evidence of physical fitness, for it has been found at Cambridge that among high-honours men, low-honour men, and men who took an ordinary pass

Digitized by Google

degree, the average physical efficiency was almost exactly the same. With a slight exception as to eyesight, "they were alike throughout; alike in their average bodily efficiency, and alike in the frequency with which different degrees of bodily efficiency were distributed among them." This being the case, Mr. Galton contends that when two candidates are almost on a par intellectually a certain weight should be given to physical superiority. One probable result of such a rule would be that more attention would be paid to the health and physical development of intending candidates, and the number of instances of broken health from over-pressure under the cramming system would be materially reduced. We believe, also, that it would considerably improve the efficiency of the services to which it was applied. Mr. Galton "entertains no doubt that if the reasonableness and feasibility of the proposed reform were widely understood, a loud demand would arise from many sides, and without arousing any opposition worth regarding, for the introduction of so salutary a measure." Mr. Galton explained the proposed system by which this could be easily carried out, and he is supported by the Civil Service Commissioners in the opinion that there would be no more difficulty in determining the relative physical capabilities of the candidates than is now experienced in the literary examination. We think the suggestion well deserves the careful consideration of the authorities, and that if judiciously brought into operation it would be productive of very beneficial results.

THE EPIDEMIC OF SCARLET FEVER IN PLYMOUTH.

SCARLET FEVER of an exceptionally fatal epidemic character has prevailed in Plymouth for nearly five months, and shows even now a tendency rather to increase than to decline. More than two months ago we called attention to the severity of the outbreak. We also pointed out that there was no legal notification of zymotic disease in the town; that, although the borough possessed an isolation hospital, there appeared to be no serious attempt to turn it to account, inasmuch as only one death had occurred in the hospital up to the end of the first week in July, although 51 deaths from scarlet fever had been recorded within the borough since the beginning of the year. During the ten weeks that have elapsed since July 6th, no fewer than 90 more deaths from this disease have occurred in the borough, making 141 since the beginning of the year, all but 3 of which have been recorded since the middle of April, soon after which the disease assumed an epidemic character. During the second quarter of this year scarlet-fever mortality was more than ten times greater in Plymouth than in the twenty-seven other great towns, the annual rate being equal to 2·21 per 1000 of the estimated population; during the eleven weeks ending last Saturday the annual rate from the disease in the borough was equal to no less than 5·8 per 1000. So remarkably fatal an epidemic of scarlet fever has not occurred in any of the twenty-eight great towns dealt with in the Registrar-General's Weekly Return since the memorable outbreak in Portsmouth in 1877. The responsibility of the Town Council of Plymouth, as the local urban sanitary authority, in the face of such an epidemic, is so heavy that we hope we are misinformed as to the statement that only four deaths have been recorded in the isolation hospital of the borough since the outbreak of the present epidemic. As we remarked more than two months ago, the local sanitary authority is seriously handicapped in having no legal system of disease notification in force in the borough; but it is difficult to acquit the authority of apathy in having neglected to turn to practical account their isolation hospital. Until the passing of the recent Act there was no system of notification in operation in London; and yet 43·8 per cent. of the deaths from scarlet fever in the metropolis during last year were recorded in hospital, whereas, if our information is correct, only 2 per cent. of the deaths in Plymouth in the present epidemic have been so recorded. It is noteworthy that Plymouth is one of those large towns which has not yet recognised the importance of appointing a medical officer of health, who, debarred from private practice, should devote his whole time to public health service.

DIAGNOSIS OF CEREBRO-SPINAL MENINGITIS BY PUNCTURE OF THE LIVER.

DR. C. BOZZOLO reports in *La Riforma Medica* an interesting case of cerebro-spinal meningitis, in which the diagnosis was assisted by bacteriological observations made on the fluid obtained by puncturing the liver. A man aged fifty-four, who had been ill for five days previously, was admitted into the clinic at Turin suffering from feverishness, pain in the right side of the neck, jaundice, enlargement of the spleen, painful enlargement of the liver, bronchitis, and albuminuria. A rigor occurred more than once. Except the pain in the neck and vomiting, no symptom whatever of meningitis existed. Six days after admission the patient died, having been slightly delirious for the previous forty-eight hours. Diagnosis being difficult, the author had on the fourth day after admission made an exploratory puncture of the liver, which was still painful. The blood extracted showed by cultivation and after experiments on animals the existence in it of Fraenkel's diplococcus of pneumonia. This result, in the absence of pneumonic and pleuritic symptoms, with the existing pains in the neck and vomiting, encouraged Bozzolo to diagnose meningitis, a diagnosis which was confirmed by the post-mortem examination. In addition to the morbid changes in the meninges, gall-stones and acute endocarditis were found.

THE USE AND ABUSE OF ICED DRINKS.

ICES and iced drinks have come to be taken so commonly and as a rule without obvious ill-effects that one is hardly prepared for the fatal consequences which in certain cases appear to follow this form of indulgence. The latest recorded instance of death from this cause occurred quite recently in Paris, where Mr. Ira Paine, a well-known American marksman, is said to have succumbed to the effects of drinking two glasses of iced beer. In order to understand the rational method of such an accident we need only recall the consequences of applying cold to other regions—namely, temporary suspension and subsequent excess of the vital processes, chiefly those of the circulation. There is a chill anæmia followed by local congestion—that is to say, the same changes in varying degree that we find occurring in a limb after frost-bite. As in the latter condition, also, we may expect the tendencies and processes of disease to be modified by circumstances. Increase of age, arterial rigidity, fatigue of the circulatory apparatus, the quantity and quality of blood in the vessels, the amount of ice, and the suddenness with which it is taken, are all accordingly matters of importance in this connexion. At any time the avoidance of undue chill to the gastric mucous membrane is the first consideration. It therefore becomes intelligible why the safe consumption of ice stands in a direct ratio to the vigour of the general and especially the gastric vascular tone, to gradual and moderate ice consumption, and to the freedom of circulation in the stomach. This reasoning explains the comparative tolerance of ice in young persons, its usually harmless effect when taken during digestion of a substantial meal, and its utility in sthenic fevers, where the blood-flow is everywhere active. It likewise justifies

Digitized by Google

the prudent custom of sipping iced fluids, through a straw for example, thus leaving time for the mucous membrane to recruit its vascular tone at frequent intervals. The habit of quaffing iced beverages in large quantities, as the case we have quoted proves, is by no means free of risk; nor, we may add, is that, so common at evening entertainments, of swallowing ices without other refreshment.

DEFORMITIES OF THE JAWS AND TEETH IN IDIOTS AND OTHERS.

THE association of the V- and saddle-shaped jaw with idiocy has been frequently pointed out in papers such as those of Cartwright, Oakley Coles, Ireland, and Langdon Down; but, according to the statistics of Dr. Talbot of Chicago, these are not the only forms of irregularity met with, nor is it true that idiots present the most aggravated deformities of jaws and teeth. In his tables he excludes those deviations from the normal which might be considered due to a local cause, and only takes those of constitutional and developmental origin. The subdivisions comprise large jaw, protrusion of lower jaw, protrusion of upper jaw, high arch, V-shaped arch, thumb-sucking, saddle-shaped arch, and small teeth. Of nearly 2000 cases examined in idiot asylums, almost one-half of the whole number had irregularities of the jaws and teeth, whereas in 1000 cases of healthy children only 22 per cent. suffered in this way. Next, taking 2000 cases of deaf and dumb persons, 45·3 per cent. presented oral deformities, and of a small number of cases in asylums for the blind there were 50 per cent. Examinations of the mouths of 700 insane patients revealed the fact that only about 12 per cent. were irregular, and these were among cases of the congenitally insane, or those who had become insane early in life. Dr. Talbot observes that there has been brought forward evidence to show that when idiocy appears in a family other members may be found scrofulous, deaf, dumb, blind, or insane, showing that the conditions indicating neurotic tendencies have been transmitted through generations; and while specialists have generally recognised only one common feature—a very low grade of cerebral development—his investigations concerning the osseous system in its relations to the irregularities of the jaw and teeth show a lesion common to all those conditions. The small percentage of deformities in the insane examined is due to the fact that, with few exceptions, insanity does not appear in the individual until the skeleton has attained its normal development. Further details will be found in the July number of *The Dental Cosmos* (Philadelphia).

FATALITY IN A MIDWIFE'S PRACTICE.

MR. WYNNE BAXTER investigated at the Town Hall, Limehouse, the circumstances of the death of Eleanor Bumforth, who was confined on Sunday, Sept. 8th, became ill with diarrhœa &c. on Wednesday, Sept. 11th, and died on Friday, Sept. 13th. She was the daughter of a midwife, who said that she did not deliver her daughter, though it was admitted that she came and examined her, and, according to the evidence of Mr. Talbot, remained with her for about an hour. The serious part of the investigation was the tracing of six cases of death in childbed from about July 24th, all of which had been attended more or less by the midwife. On July 24th she attended Mrs. Sparrow, Copenhagen-street. She died. A medical practitioner was called in, and told the midwife she ought not to go out for a fortnight. But she attended Mrs. Ward on Aug. 1st, who complained the following day of pain in the stomach and vomiting, and died on Aug. 5th; and so on with other cases all remarkably alike. There was an inquest on Mrs. Ward, at which the midwife was warned by the coroner to desist at least a fortnight. Mr. Talbot, who was called to the last case, attributed the cases to some constitutional fault in the midwife, who had diseased bone in the mouth. The only notice of the fatalities and of the various warnings which she took was to wash her clothes in Condy's fluid and go away for a week from August 7th. When a patient sent for her on the 14th she replied that she ought not to go; but the patient saying that she had no fear, as people had to die when their time came and not before, she went. In the end the coroner spoke very gravely to her, and said that if she attended a case within three months he would have her committed for manslaughter. It must be admitted that he dealt leniently with her, and that her conduct was exceedingly blamable. One of our contemporaries heads the inquest "A Strange Epidemic in Limehouse." But there is really nothing strange about it but the persistence of the woman in going about spreading disease after both the coroner and at least two medical men had fully warned her. It is one more and very sad illustration of the state of midwives' midwifery. It is discreditable to the Home Office that legislation is so long delayed insisting on some proofs of education and intelligence in midwives. Until such legislation is earnestly set about, we must consider our legislators as much to blame as the ignorant women who think to disinfect their persons by merely washing their clothes in Condy's fluid. One of our contemporaries seems anxious about doctors and their personal disinfection. We can assure it that the disinfection of obstetricians has become one of the fine arts, and has reached such perfection that even in Lying-in Hospitals septic mortality is almost abolished. The difference between a medical man and a midwife is that the one is educated and the other is not, and that he is quick to recognise any indications of sepsis, and to deal with them *secundum artem*. It is gratifying to know that with very little intelligent trouble this risk of midwifery may be abolished. And every obstetric practitioner, male or female, should regard the abolition as one of the prime duties of practice, at whatever personal inconvenience.

UNUSUAL MODE OF SUICIDE.

ON the 28th of August an inquest was held at Lincoln on the body of a woman, aged thirty-eight, who had been found dead in her room early that morning. The medical man who was first called in found the woman lying on the floor, apparently dead; blood had flowed from the nose and mouth, and there was much blood about the room, especially on the carpet. Examination of the mouth revealed the presence of the sharp broken end of a hand mirror, which was just within reach of the forefinger, was about four inches in length, and was removed with some difficulty. A hand looking-glass had been found on the dressing-table; this was spotted with blood, and the handle had been broken off close to the mirror. At the post-mortem examination a sharp piece of wood, about two inches in length, was found lying between the posterior wall of the œsophagus and the cervical spine; this fitted the mirror and the broken handle previously removed. There was an opening in the lower part of the pharynx near the commencement of the œsophagus, through which the wood had penetrated, and some of the muscles in front of the spine were lacerated. Death was ascribed to suffocation by pressure of the foreign body on the larynx. It was supposed that suicide had been committed by the deceased whilst under the early effects of opium poisoning, that she had forced the mirror handle foremost into the mouth, and that it had broken at the junction of the handle and mirror. From the description of the broken handle, and the way in which it was splintered and impacted in the pharynx, the idea is suggested that the woman might have held it in her mouth and fallen forward on the floor, thus driving it forcibly against the spine, and

Digitized by Google

causing the point of the handle to run downwards in front of the cervical vertebræ. It is difficult to imagine anyone of sufficient strength and determination to produce the result described without some such assistance. The finding of the mirror on the dressing-table lends support to the view given in the medical evidence, but does not disprove the other supposition—either implies great determination on the part of the woman. Almost all the injuries causing perforation of the pharynx, excluding gunshot wounds, have been produced by a person falling forward on the ground and so forcing a pipe or similar thing into the mouth, or a blow has been struck by someone and a similar result produced, the blow having struck the foreign body and forced it backwards.

CENTENARIANISM IN IRELAND.

THE Registrar-General of Ireland, in his twenty-fifth annual report, which has just been issued, states that the deaths registered during the year 1888 included no fewer than 208 of persons stated to have been aged upwards of one hundred years at the time of their decease; this number included 87 males and 121 females. Such statements in the Death Register would not, if uncorroborated, inspire much confidence, bearing in mind the usual result of the investigation of similar statements in all parts of the world. Dr. Grimshaw, however, proceeds to state that, "further inquiry having been made, it was ascertained that the ages of the centenarians as given in the records were in every case confirmed." Such an unwonted result of the investigation of claims to centenarianism deserves fuller notice. It would have been interesting to know the precise nature of the investigation, and of the evidence accepted as confirming the accuracy of the statement in the Death Register; also the precise stated age of each of these 208 centenarians might well have been placed on record. The English report for 1888 has not yet been issued, but it is worth noting that in 1887 the deaths of only 60 reputed centenarians were registered in England and Wales, little more than 2 per million of the estimated living population. In Ireland, however, the deaths of centenarians in 1888 were, Dr. Grimshaw reports, 208, and thus more than 43 per million of the population! This is certainly a startling announcement. It may be pointed out that the numbers of centenarians in the two sexes show an unwonted equality in Ireland, being in the proportion of 1·4 females to 1 male; whereas in England and Wales the proportion in 1887 was 3·6 females to 1 male. Measured by their proportion to the deaths of persons aged upwards of seventy-five years, the Irish figures suggest further evidence of untrustworthiness. The Irish report for 1888 records the deaths of 16,611 persons aged upwards of seventy-five years; the 208 reputed centenarians were therefore equal to 12·5 per 1000 of those who died above the age of seventy-five years. If we measure the 60 reputed centenarians in England and Wales in 1887 in the same manner, we find that they were equal to only 1·1 per 1000 of the recorded deaths of persons aged upwards of seventy-five years. We are faced, therefore, with two alternatives. Either we must believe that of persons aged upwards of seventy-five years more than twelve times as many attain the age of one hundred years in Ireland as in England, or we must decline to accept as trustworthy the statement of the Registrar-General of Ireland that 208 undoubted centenarians died in that country during last year. Indeed, further ground for doubting the accuracy of the Registrar-General's report as to Irish centenarianism is afforded by the fact that the death-rate in Ireland among persons aged upwards of sixty-five years (stated by Dr. Grimshaw to have been 97·0 per 1000 in 1888) has in recent years somewhat exceeded that which has prevailed in England and Wales. If the mean death-rate among persons aged upwards of sixty-five years is higher in Ireland than in England, there is the best ground for disbelieving that the proportion of survivors to the age of one hundred years is larger in Ireland than in England.

INTESTINAL OBSTRUCTION.

DR. GELPKE reports in the *Correspondenzblätter für Schweizer Aerzte* four cases of intestinal obstruction, of which two had been operated on, one with success, and two had been successfully treated with metallic mercury. From these cases he concludes that quicksilver is a valuable remedy in cases of obstruction, and that the metal seems to be quite innocuous to the system if not too long retained. It had been so retained in one of the two cases in which four teaspoonfuls of quicksilver had been given, and the fæces and urine of the patient contained the drug for twelve weeks; there were other distinct symptoms of mercurial poisoning, such as great emaciation, excitement, loss of hair, and some stomatitis. The other patient, on the contrary, showed no signs of mercurialism whatever. He considers that in hernia it is generally advisable to commence the abdominal section from the orifice of the sac. Finally, considering the uncertain and not very successful results of laparotomy, he would not operate before other means, such as quicksilver, have been tried for from four to six days.

Dr. S. V. Reitz, in the *Centralblatt für Chirurgie*, reports the case of a labourer suffering from obstruction of the bowels, who, after three days' fruitless administration of purgatives, was brought to the hospital. Fæcal vomiting was present, and a tumour could be felt on the left side of the umbilicus. Enemata of water by the long tube, though as much as six pounds of water were injected, were unsuccessful, but the vomiting and sickness improved under repeated washing out of the stomach. The next day the patient was considerably worse, and fæcal vomiting returned, with cold perspiration, restlessness, meteorismus, a pulse of 120, and a temperature of 100°. After the enema with the long tube had been again used, and the stomach repeatedly washed out, without any improvement, seven drachms of bicarbonate of soda in five ounces of water were injected into the rectum, followed by three drachms of tartaric acid in the same amount of water, and the anus closed. The patient, who was on his knees and elbows, complained at once of severe abdominal pains, and in five minutes the injection came away with exceedingly offensive flatus. Shortly afterwards the patient felt considerably better. In three hours the enema was repeated with half the previous doses, and was shortly followed by a large loose motion, and by a second later on. The patient completely recovered.

VACCINATION MEMORANDA.

AMONGST the papers contributed last year to the Australian Association for the Advancement of Science is one by Dr. Ashburton Thompson on the classification of persons who have been exposed to the infection of small-pox, so as to show the relation between the incidence of the disease and different degrees of protection by vaccination or by a former attack of small-pox. After explaining at some length the principle of the method of classification adopted, an analysis is given of the state as to vaccination of, and the incidence of small-pox upon, the 312 passengers who were landed in 1886 at the quarantine station, Port Jackson, from the steamship *Preussen*, on which small-pox had taken place. Of 19 persons who were unvaccinated, 4 only escaped, the percentage of attacks being 78·9, and the rate of fatality being 60 per cent. of attacks; all the attacks were either severe or moderate, none being slight. Of 55 persons who had been both vaccinated and revaccinated, the percentage of attacks was 7·3; none of the

Digitized by Google

cases were fatal, and all the attacks are entered as either slight or very slight. Of 103 passengers and crew who had been primarily vaccinated, and who had a sufficient area of scar of good character, 20, or 19·4 per cent., were attacked, no deaths occurring amongst them. All those attacked were over fifteen years of age. Of 47, who whilst having scars of good character, exhibited an insufficient area of foveation, 9, or 19·1 per cent., were attacked, but no deaths occurred. Of these, 1 took place under and 8 over fifteen years of age; the attack under fifteen years of age being recorded as very slight. There were 27 persons who, with a sufficient area of scar, exhibited scars of a "bad" character. Of these, 5, or 18·5 per cent., were attacked, and again none died. All these attacks were in individuals over fifteen years of age. And, lastly, there were 32 persons whose vaccination was imperfect, both by reason of deficient area and bad character of the scars. Of these, 11, or 34·3 per cent., were attacked, and the deaths were 3, giving a fatality percentage of 27·2. All these attacks also occurred in persons over fifteen years of age. The results shown are very striking, in so far as they afford an indication of the great power of vaccination in preventing death from small-pox, even at a distance from the date of vaccination. Thus, even an imperfect vaccination saved all under fifteen years from death by small-pox. So, also, only one single attack below fifteen years of age occurred amongst any of the vaccinated.

CHURCH VAULTS, CHURCHYARDS, CEMETERIES, AND BURIAL REFORM.

A CIRCUMSTANCE has recently occurred which is calculated to add considerable weight to the remarks made in a recent issue of THE LANCET, and to provide a terribly forcible argument in favour of simple earth-to-earth burial. For some time past the members of the choir and congregation of St. Mary's, Woolnoth, have complained of sore throats and other ailments as the results of attending service in that church, the air in which has been of late much vitiated, and unpleasant odours have been very perceptible. The examination of the church by sanitary experts has resulted in its being closed, it being considered unsafe for anyone to remain in it for any length of time. Investigations are now being made to ascertain the source of the foul air, which is supposed to arise from the bodies deposited in the vaults below. This is one of the churches the vaults of which were inspected by the late Dr. Waller Lewis about the year 1850, and of which he reported: "The vaults I have visited up to the present time are generally in a very disgraceful condition. ..... In St. Mary's, Woolnoth, the churchwarden thinks there are about 1100 coffins; the sexton considers there are not more than 500. In this church leaden coffins have only been used (except in the chancel) since the regulations of the General Board of Health enjoining the use of lead." Unless, therefore, something has been done since that date to remedy the condition of the vault and its contents, there is only too much probability that the bad odours now perceptible arise from bodies interred in wooden coffins, without lead, in vaults above which living persons have till recently assembled every Sunday to worship. Not long ago there were complaints of similarly unpleasant odours being perceptible in another city church. Nothing can be clearer than the duty of the authorities, which is to have these vaults examined with every due precaution; either to entomb in charcoal and concrete all the remains which may be found; or, better still, to remove them to some suburban cemetery for burial in the earth. Moreover, now that two city churches have been found unwholesome in consequence of the vaults beneath, would it not be a wise precaution to anticipate the possibility of these evils arising in other city churches, by having an inspection of all those having vaults in which dead bodies are deposited, with a view to their sanitary entombment or removal. That prevention of these sore throats and other ailments would be better than cure must be obvious. In connexion with this subject, a letter from the Dean of York, chairman of the Council of the Church of England Burial Reform Association, comes to hand very opportunely. It is shown that the members of the Association are concentrating all their energies on two principal points—burial in perishable coffins, and in simple "earth-to-earth" graves. As the venerable Dean remarks, "the Burial Service in our Book of Common Prayer offers suggestions of a mode of disposing of the dead which has been declared by scientific men to be in accordance with sound science and sanitary law, and which, if properly and completely carried out, renders overcrowding impossible." In the Burial Service there is no mention of a coffin, the terms used being "corpse" or "body." The body is to be made ready to be laid into the earth, and earth is to be cast upon the body. The consequences of acting in direct defiance of all rubrics, all sanitary laws, and all reason are shown in such cases as St. Mary, Woolnoth, now, and previously in St. Andrew's, Holborn, St. Martin's-in-the-fields, and many others. Dr. Purey Cust observes towards the conclusion of his admirable letter: "Graveyards should be gardens where the dead are buried side by side, each succession of human bodies passing away into air and ashes, the earth being thus ready every succeeding generation to perform its beneficent action again. Thus natural laws will have been observed, and the earth which is the best deodoriser and antiseptic known, and the receptacle of all creatures which have lived and died, will have acted as the medium through which the air descends and performs its purifying and disintegrating action to reascend in new combinations and nourish fresh life."

USELESS INQUESTS.

WE have frequently in our columns called the attention of our readers to the uselessness of inquests which are held without a post-mortem examination and medical testimony as to the cause of death. We have had our remarks strikingly exemplified by an inquest held a fortnight ago at Lowton, near Newton-le-Willows, Lancashire, by Mr. Husband, the deputy coroner for one of the Lancashire divisions of the county. The subject of inquiry was the strange death of a boy four years of age named Jesse Jones, the son of a navvy employed on the Ship Canal Works. The mother stated that the deceased had been always healthy, except a slight attack of bronchitis which he had the year before, and from which he soon recovered. She had taken him to a neighbouring village, and returned home at 4 o'clock in the afternoon. He then went into the yard to play, but soon came in again, saying that he felt "as drunk as anything." She gave him some tea. He was taken to bed at 9.45 P.M., and he slept all night. Next morning, as he said he did not feel well, he was not sent to school, but allowed to rest on the sofa. Subsequently he had a dose of senna tea, which he vomited, and then some warm tea was given to him. At 2 o'clock in the afternoon he woke up, and began to "shake and tremble" and to froth at the mouth. A doctor was sent for, but the child died before his arrival. The boy was insured for £3 in the Prudential Society. Questioned by the coroner, she said there were no berries in the yard, and he had no sweets in the village. He fell on his head whilst playing in the yard, and this caused his head to ache. A neighbour testified to the boy dying in her presence in a fit. The deputy coroner said the symptoms pointed to deceased having eaten something poisonous—the pods of laburnum trees, or something of the kind. He could hardly see that the death was from natural causes. The jury could return one of four verdicts:

Digitized by Google

1st, accidental death; 2nd, death from natural causes; 3rd, death from taking improper food; or, 4th, an open verdict, which was to say there was nothing to show the cause of death. After some discussion the jury returned the following verdict, "Death from natural causes, the nature of which the evidence does not show." We cannot imagine a more futile inquiry. Surely a necropsy was requisite in order to ascertain whether the death was from natural causes or not. We might observe here that, in a case of this nature, if the coroner is satisfied, from inquiries made by the police on the spot, that there is no suspicion of foul play and no necessity for a post-mortem examination or medical testimony, he might save the time of twelve intelligent jurymen, and order the burial without summoning them to hold an inquiry which bears no fruit, and is useless so far as the finding out of the actual cause of death is concerned.

CARELESS DEATH CERTIFICATION AND VACCINATION.

VACCINATION is a convenient explanation of all sorts of constitutional weakness, and exempts parents from the reproach which might otherwise belong to them. At Cardiff lately the registrar directed the attention of the medical officer of health to the death of a child twelve months old registered as "caused by phthisis consequent on vaccination." The mother had chosen the child from whom the lymph was taken, in London, for its healthy appearance. But she somehow took it into her head that the vaccinator was to blame, and, unfortunately got a medical man to put into his certificate, merely on the strength of her fancy, that the phthisis was caused by vaccination. We can imagine the delight that would run through the anti-vaccination circle at Cardiff by such a case. Fortunately the medical officer of health, Dr. Walford, took the case in hand and got at the facts. He found "the mother herself had twice suffered from inflammation of the lungs, some of her brothers and sisters were consumptive, her own mother died from consumption, and sixteen of her mother's brothers and sisters had also died from the same complaint." With such a history of course even anti-vaccinationists cannot contend, and the case makes one more addition to the pile of absurd conditions which mostly constitute anti-vaccination literature. We must join our contemporary, the *South Wales Daily News*, in expressing at once regret that a medical man could have written such a certificate as was given in this case. The value of medical certification depends not on what comes into the mother's head but what comes out of the doctor's educated mind. On hearing the facts brought to light by Dr. Walford, the medical man at once admitted that the vaccination theory could not be maintained, and that it had been inserted wholly on the mother's statement.

A WARNING TO HOSPITAL VISITORS.

BY this time not only physicians and trained nurses, but a large proportion of the general public, are familiar with the fact that a fluid and light diet in typhoid fever is practically a matter of life and death. Unfortunately, an equally large or even larger number of persons are still grossly ignorant on this elementary and most important point, as the sequel shows. A few days ago a young man, a patient in the London Hospital, about the fourth week of this fever, partook of some grapes which his father brought him—of course, against hospital rules. The result was vomiting, with consequent fatal perforation. In this case it is difficult to say where blame should chiefly be attached. The patient was at that critical stage in the disease when appetite awakes with the advent of convalescence, but he must nevertheless have known pretty well what food for him was contraband. For the father's guidance there were placards in abundance throughout the hospital, forbidding visitors to bring into the wards any food save tea, sugar, and butter; yet he never noticed them! This is the most remarkable part of the story, yet, strange to say, such carelessness as this is of every-day occurrence. Partly, no doubt, from inability to read, and partly from mere heedlessness and want of the sense of personal responsibility, hospital patients and their friends daily ignore the simplest rules inscribed on admission cards and letters for their guidance. Much inconvenience results—though not often, let us hope, such mishaps as that above mentioned. A very moderate concentration of attention on these necessary details would go far towards averting both lesser and greater evils. It is therefore to be hoped that the lessons of this deplorable incident will not be lost upon the class whom it most nearly affects.

SURGEON CRIMMIN AND THE VICTORIA CROSS.

THE Queen has been pleased to bestow the rare distinction of the Victoria Cross upon Surgeon John Crimmin, L.K.Q.C.P.I., L.R.C.S.I., of the Bombay Medical Service, for the following act of bravery:—"Lieutenant Tighe, 27th Bombay Infantry (to the Mounted Infantry to which corps Surgeon Crimmin was attached), states that in the action near Lwekaw, Eastern Karenni, on Jan. 1st last, four men charged with him into the midst of a large body of the enemy who were moving off from the Karen left flank, and two men fell to the ground wounded. He saw Surgeon Crimmin attending one of the men about 200 yards to the rear. Karens were round the party in every direction, and he saw several fire at Surgeon Crimmin and the wounded man. A sepoy then galloped up to Surgeon Crimmin, and the latter joined the fighting line which then came up. Lieutenant Tighe further states that very shortly afterwards they were engaged in driving the enemy from small clumps of trees and bamboo, in which the Karens took shelter. Near one of these clumps he saw Surgeon Crimmin attending a wounded man. Several Karens rushed out at him. Surgeon Crimmin thrust his sword through one of them and attacked a second; a third Karen then dropped from the fire of a sepoy, upon which the remaining Karens fled."

THE CARPET-BEATING ANNOYANCE.

NO intelligent person, not even the mistress of a house absorbed in the business of spring cleaning, will deny that the beating of carpets is, for various reasons, a social nuisance. The addition of household dust and particles of woollen texture imports nothing of advantage, but often more or less that is injurious, into the air we breathe. It has been urged that germs of disease are thus distributed in the atmosphere. This is true enough, though happily the danger of infection from such a source is in all large open spaces reduced by the action of oxygen and aerial currents. Another drawback is hardly less noteworthy—namely, the disturbance of rest caused by the drum and rap of incessant switching. No person possessed of a sensitive nervous system—above all, no invalid—need hope for quiet while the work goes on. An attitude of uncomfortable disinterestedness is all that remains for him. His evil may be someone's good, at all events if carpet-beating is necessary. To some extent it probably is so. Time, distance, cost, and the want of sufficient apparatus combine to render as yet more or less uncertain the aid of other mechanical methods. If these were now easily and universally applicable, the beating system would not have a leg to stand on. For a time we fear it must continue; but in mitigation of its evils and annoyances it is only fair to allow to the com-

Digitized by Google

plaints of the afflicted, if supported by a reasonable amount of proof, a power stronger than that of remonstrance and akin to that of a legal veto.

PROSECUTION FOR NON-NOTIFICATION OF INFECTIOUS DISEASE AT LEICESTER.

WE have before pointed out that Leicester, which is so jealous of interference with the liberty to have small-pox, has no compunctions about curtailing liberty in other ways in the interest of public health. The Sanitary Committee has just had its first prosecution for non-notification. The case was that of a jeweller who had a son labouring under scarlet fever, and he was charged first with neglecting to give notice of the fact to the sanitary authorities, and, secondly, with exposing the boy in his shop without proper precautions. The town clerk said the Sanitary Committee considered the case as one of importance to the borough. The proceedings were taken in no vindictive spirit, but to give fair warning to the public that even where there is no medical man in attendance, as here, the parent will be held responsible and the full penalty demanded. The full penalty was not inflicted in this case, but a fine of £1 in respect of each charge, or fourteen days' imprisonment in default. The prosecution will do good. It will commit Leicester more and more to an observance of the law, or at least expose it to the charge of inconsistency in not observing the whole law, and it will let the public know that the not calling in a medical man in no way exonerates them from the duty of notifying. The father knew of the nature of the disease, for he had given information to the school at which his boy attended. It is well known that the milder cases of scarlet fever require very careful medical management as well as others. But there is a tendency to forget this among the working classes and to suppress the fact of such cases existing. Leicester is one of the towns which had the system of notification under a local act.

TRICUSPID STENOSIS.

FROM some facts collected by M. Leudet (of Rouen) and his father, the late Professor Leudet, the comparatively rare condition of stenosis of the tricuspid orifice (*L'Union Médicale*, No. 96) may be either congenital or acquired. The former arises either in fatal endocarditis or from a malformation producing an excessive amount of muscular tissue at the auriculo-ventricular junction. In consequence of the stenosis, there may also be patency of the foramen ovale and incomplete formation of the ventricular septum; sometimes it is associated with pulmonary stenosis or lesions on the left side. Cyanosis is the most frequent symptom; and a systolic bruit, rarely a diastolic, may be produced; whilst the enlargement of the right auricle may occasionally be detected by percussion dulness crossing the sternum. It is obvious that the diagnosis of the condition is hardly to be determined, from other forms of congenital malformation. M. Leudet has collected details of 114 cases of acquired tricuspid stenosis, 86 females and 22 males (in 6 the sex not stated); and in 57 no antecedent disease, such as rheumatism, chorea, typhoid fever, or scarlatina, was noted. The degree of stenosis may be considerable, and it may be produced by—(1) cohesion of the valves; (2) true stenosis of the orifice; (3) obstruction by vegetations, &c. The first often is the most frequent—"a chronic, slow, silent endocarditis, generalised rather than deep, vegetating but little, yet adhesive and plastic, tending to cause the damaged valves to unite at their margins." In only 11 cases out of the 114 was the tricuspid stenosis solitary; usually there is concomitant mitral stenosis, which is always more marked than the tricuspid. Presystolic thrill and bruit at the xiphoid and above may be present, but do not from these observations appear to be common.

THE LIVERPOOL ABATTOIRS.

THE public mind in Liverpool is somewhat exercised because the Abattoir Company have petitioned the Corporation for the renewal of their present lease and the grant of further land for the extension of their premises. The *Liverpool Courier* protests strongly against the granting of these privileges, on the ground that the abattoir is in the centre of the city, and its existence tends to depreciate the property in the neighbourhood. Land which has been cleared of houses has remained idle and profitless, and the houses which still exist are said to be unfit for habitation—the businesses which are carried on in connexion with the abattoir, the gut-scraping, blood-boiling, hide-dressing, offal-salting, &c., constituting a serious nuisance. If this statement is free from exaggeration, it certainly behoves the authority to find another site. The business of killing animals for food should not be carried on in the midst of a large population, and a public abattoir thus situated might readily become a more serious nuisance than even private slaughterhouses. London, in spite of the improvements which have been effected, is still conscious of the inconvenience which results from the driving of cattle through the streets and from their slaughtering in the midst of dwelling-houses. The only remedy is the public abattoir; but this should be situated in a proper locality, sufficiently remote to enable the business to be conducted without offence, and so placed that animals arriving by sea or by land can be conveyed there without necessitating their passage through the streets. The need for London to change her ways is so obvious that the proceedings at Liverpool will be closely watched, for we are convinced that an authority which has freed itself from private slaughterhouses will never again revert to their use. We do not doubt the capacity of the Liverpool Corporation to find a solution to their difficulty.

CHOREA ATTRIBUTED TO POISONING BY IODOFORM.

THE twenty-fifth annual report of the Jenner Hospital for Children in Berne contains a report of a secondary retro-pharyngeal abscess in a boy of six years, who was suffering from disease of the cervical vertebræ. Professor R. Demme opened this abscess, and a second, which had reached to the middle of the right clavicle. A little iodoform bougie was introduced in the fistulous canal, and the wound dressed with iodoform powder and gauze. Three days afterwards the boy suffered from headache and complained of being sick, but the dressing was not changed, and a second iodoform bougie was introduced four days later, when convulsions began to occur gradually, passing on to chorea. The iodoform was then omitted from the dressing, and the chorea disappeared after a fortnight. A few weeks later another practitioner dressed the same case with iodol and iodol gauze, and again chorea appeared, lasting for three weeks.

THE DESTRUCTION OF SEWER AIR IN LEEDS.

THE desirability of arranging for the destruction of sewer air is engaging the attention of the Sanitary Committee of the Corporation of Leeds. One proposal is to utilise the refuse which comes from the premises of certain manufacturing chemists by removing it to a number of cisterns to be constructed along the lines of sewers, into which it would be made to flow slowly by day and by night. The waste refuse in question contains a large percentage of sulphate of iron, and it is assumed that if it mingles with the sewage in a moderate amount only it will not damage the joints, whereas it will prevent fermentation and decomposition, and in this way stop the formation of unwholesome effluvia. Another proposal is to ventilate the

Digitized by Google

sewers by means of shafts so arranged that the heat passing up these shall both add to the ventilation and destroy all the noxious properties of the sewer air. Before embarking in either scheme, it has been decided that experiments should be made in a certain section of the borough as to both methods, and that before even these experiments are commenced the sewage itself and the gases evolved by it should be properly examined and analysed, so that the committee may know precisely with what they are dealing.

THE OUTBREAK OF DIPHTHERIA AT EAST HADDON.

THE outbreak of diphtheria in the Northamptonshire village of East Haddon shows no sign of dying out. The parish of this name is distinctly rural, having, according to the last census report, an area of 2572 acres, and a population at the date of the last census of 752 persons against 726 at the previous census in 1871. In this small rural community no fewer than 17 deaths resulted from diphtheria or diphtheritic croup between Aug. 26th and the 11th inst.; 8 deaths occurred on the four days ending Aug. 30th, after which the number of deaths decreased, no more than 1 occurring per day until the 11th inst., when 3 deaths took place. The National School has been fitted up with 14 beds, and further accommodation has been secured should necessity arise. So fatal an outbreak in so circumscribed an area should, if made the subject of immediate investigation, throw useful light upon the causation of such rural epidemics The increase of our knowledge concerning the causation and behaviour of this disease is becoming daily more important, owing to the general increase of diphtheria mortality in this country.

ANTI-VACCINATION IN ST. PANCRAS.

AN evening contemporary states that the anti-vaccinationists in St. Pancras have given notice of their intention to take aggressive action with regard to the administration of the vaccination law in that parish. The guardians of St. Pancras have, we understand, followed the advice of the Local Government Board to refrain from repeated prosecutions of the same individual, and have in practice limited themselves to one prosecution, unless it is proved that the house or neighbourhood in which the unvaccinated children reside is visited by or threatened with an epidemic of small-pox. But this action does not satisfy the anti-vaccinationists, who would prefer to see the law not enforced at all. What course the anti-vaccinationists have decided to take is not stated, but we doubt if the guardians will depart from their usual procedure because difficulties are put in their way. They will, we anticipate, make no change until the Royal Commission has reported, and the result of the inquiry now being made is known. They will then have the conclusions of the Commission to appeal to as guide for their future conduct.

IODOFORM IN MALIGNANT PUSTULE.

DR. E. RINONAPOLI (*Bolletino della R. Accad. Med.-Ch di Napoli*, No. 3, 1889), gives particulars of several cases of malignant pustule treated by the subcutaneous injection of a solution of iodoform in ether. Dr. Rinonapoli began this method in 1886, some thirteen months before Senger's work on the antiparasitic action of iodoform appeared. The method employed is that of several injections into and around the seat of the pustule of a 10 per cent. solution of iodoform in ether. The pain attending the injections is of severe burning character, but soon passes off. The beneficial effects are rapid in their appearance. In three or four hours after the injections, even in advanced cases, the fever lessens, the swelling round the pustule disappears, the tongue becomes clean, and the patient is able to sleep and to take food. The treatment appears to be of distinctly specific character, and to arrest at once the growth and multiplication of the charbon bacillus. If applied at the outset of the attack, the effect is said to be almost magical.

THE GAOL HOSPITAL AT JOHANNESBURG.

A CLERICAL GENTLEMAN (Rev. F. H. Fisher) has written to the Johannesburg Hospital Board to bring to the notice of the Sanitary Board the state of that portion of the gaol which is used as a hospital and the treatment of the patients there. He says: "I know not who is responsible for this place; but I have no hesitation in saying that the whole thing is a disgrace to a civilised town. In an unkept and brick-floored room, opening immediately into the courtyard of the gaol, are a dozen bedsteads, upon which lie as many patients, white and natives, young and old. In this filthy den comfort is unheard of and decency unknown. Dirty coloured blankets are the bed-coverings of men seriously ill, and cleanliness is a word taken from a dead language. The rations served out to poor fellows suffering from dysentery, enteric fever, and severe accidents consist of a chunk of bread and an equal amount of cold boiled mutton." It seems that by no means are all of the patients prisoners Even if they were, they ought to be treated with humanity; but if the charge made by the reverend gentleman is based on fact, the authorities who are responsible for the gaol hospital have a good deal to answer for, especially if, as is further asserted, contagious and non-contagious cases are put together.

WOLVERHAMPTON GENERAL INFIRMARY.

AT the recent half-yearly meeting of the governors of the above institution a resolution was carried to create the new office of honorary pathological officer, and on the motion of the chairman, seconded by Dr. Millington, the appointment was conferred upon Dr. McMunn, whose researches in pathological chemistry and allied subjects are well known. It is pleasant to find that the labours of Dr. McMunn are properly esteemed in the town in which he resides, and in affording him increased facilities for the pursuit of his studies the governors of the Wolverhampton Infirmary have shown a commendable appreciation of the importance of scientific inquiry.

ROYAL COMMISSION ON VACCINATION.

THE first Report of the Royal Commission on Vaccination, which it has been decided to issue at once, will contain all the evidence submitted to the Commission up to the date of their adjournment—namely, that of Sir John Simon, K.C.B., Dr. Wm. Ogle, Dr. Thorne Thorne, and Dr. J. H. Rauch of the Illinois State Board of Health.

SCARLET FEVER IN CAMDEN TOWN.

A PARAGRAPH is appearing in various newspapers to the effect that Bayham-street, Camden Town, is suffering from scarlet fever, and this is associated in the mind of the writer with the unwholesome condition of the Regent's Canal. Let the condition of the canal be what it may, it should be pointed out that, whether or not scarlet fever is prevalent in Bayham-street, there is no reason to suppose that it owes its existence to any "dead dogs, cats, and garbage thrown into the water." We are so much accustomed to read exaggerated accounts of the state of the Regent's Canal that we shall not be surprised to hear that its bad condition has been again overstated. But whether this is so or not, there is no reason to assume that scarlet fever has its origin in such a cause.

FOREIGN UNIVERSITY INTELLIGENCE.

Buda-Pesth.—Dr. Alex. Szénássy has qualified as *privat-docent* in Bandaging and the Use of Instruments.

Cagliari.—Dr. Lustig has been appointed Professor of General Pathology.

Cracow.—Dr. Pietrovski has been recognised as *privat-docent* in Physiology.

Kharkoff.—The number of applications for admission to the various Faculties is smaller than it has ever been before, and it is remarkable that nearly all the applications refer to the Medical Faculty, there being scarcely any students wishing to enter the Legal and Philosophical Faculties.

Kieff.—Dr. V. T. Chernoff, Director of the Olga Children's Hospital in Moscow, has been appointed to the chair of Children's Diseases.

St. Petersburg.—The number of applications for admission to the Medico-Chirurgical Academy of St. Petersburg, the most important medical school in Russia, is far greater than the vacancies. Not only have many applicants who have passed their maturity examinations at the St. Petersburg gymnasiums to be refused, but also some students of the St. Petersburg University who desire to be transferred to the Academy, which, though entirely distinct from the University and governed by the Ministry of War, in many respects fills the place of a Medical Faculty to the University.

Tübingen.—Drs. Vierordt and Wagenhäuser have been promoted to the rank of Extraordinary Professors.

Professor Weigert is about to retire from the post of editor of the *Fortschritte der Medicin.*

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Preiss of Carlsbad; Dr. Oré, Professor of Physiology in Bordeaux; and Dr. Rudolf Voltalini, Professor of Laryngology and Otology in Breslau.

FOLLOWING closely on the discussion as to the poisonous ingredient in fly-papers, we have the announcement in Swiss journals that a series of bank-notes recently issued by the Confederation, and printed in green colours, have induced in the officials who manipulated them the well-known symptoms of irritant poisoning. The matter is under investigation; but, meanwhile, those of our compatriots who may still be in Switzerland should know that the notes in question are fifty-franc notes.

THE well-known and able ophthalmologist, Professor Dr. Jacobson of Königsberg, died on the 16th inst. at Cranz, a watering-place on the Baltic. The deceased was the father of Dr. Julius Jacobson, likewise a well-known ophthalmologist, who has been residing in London for several years past.

SUNDERLAND AND BISHOPWEARMOUTH INFIRMARY. The ninetieth annual report of this institution again showed a considerable increase in the number of patients treated in the infirmary, the total number being 4833, or an increase of 933 compared with the preceding year. The deaths numbered 64, which was equal to a rate of 3·6 per cent. as against 6 8 and 3·9 per cent. last year. The total income from all sources was £8122 16*s.* 6*d.*, and the expenditure £5289 15*s.* 10*d.* The committee recommended that the surplus be utilised in repaying the balance of the amount borrowed from capital, with the sanction of the Charity Commissioners, in 1881. The report was adopted. The committee desire to remind those interested in the work done by this institution that as soon as the Hartley Memorial Wing, which is almost completed, is occupied by patients, additional funds to the amount of £2000 per annum will be required.

ICE SPOILS FISH.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. III.

IN considering the preservation of fish, its red muscular fibres are comparatively so few that for practical purposes the study of the pale fibres is sufficient. Whilst in the higher animals used as food the muscles are arranged in close, thick, firm bundles of long fibres, in fish nearly all the muscles are in the form of loose, short, soft bundles arranged in narrow rings in a zig-zag fashion, separated from each other by delicate partitions of thin connective tissue. Except in the eel, salmon, and mackerel, fat is usually absent in fish. The flesh of salmon yields from 63 to 68 per cent. of water, whilst that of ordinary white fish furnishes from 75 to 82 per cent., which are much larger proportions of water than is contained in meat. Not only in the intestinal tract, but also in the blood, lymph, and tissues of healthy *living* sea and fresh water fish, active and multiplying bacteria are found. Though fish up to a certain point apparently are able to tolerate the presence of these bacteria in their blood and lymph, yet, should the vitality of their tissues become lowered by confinement, injury, starvation, or disease, the fish will probably be overcome and die. The same applies to external and internal parasites, which almost invariably frequent healthy fish, who, up to a certain point are also tolerant of these parasites. On death fish readily absorb water from moisture, whether naturally in the atmosphere or foolishly supplied by the chronic conventional customs of using melting ice, as well as by the continual watering of fish on the fishmongers' slab. How excessively deleterious the absorption of the moisture will be is apparent upon recollecting the filthy state of the fish boxes, barrels, and baskets in the equally filthy fish boats, fish markets, and some fishmongers' shops.

Though from time immemorial the Norwegians, immediately on capture, have always *bled* their fish by incisions just under and behind the gills, the usual situation of the heart in most fishes, or else above the tail, and then at once *gutted* their fish, yet British fishermen seem still unwilling to listen to and to learn this wise economical practice. The Dutch, introducing the Scandinavian plans of bleeding before clotting and gutting herrings on capture, together with the plan of pickling and curing herrings re-invented by an Englishman, Will Blenkinson, secured for their countrymen from the fourteenth to the eighteenth centuries the virtual monopoly of the marine mastership of the world, including its carrying and export commerce. Because of its rapid putrefactive contagion, I propose that no unbled and ungutted dead fish should be allowed to enter any fish market or fishmonger's shop in the United Kingdom. Living cattle with certain contagious diseases are slaughtered by Government authority. What butcher would dream of cutting up meat from an ungutted or uncleaned carcase? Though fish is pre-eminently more prone to early putrefaction than meat, nevertheless the conventional British fish markets and many fishmongers' shops stink from avoidable causes, and thereby spoil any unspoilt fish in their vicinity. A slaughterhouse would be properly objected to in the heart of most towns; nevertheless, fish markets and fishmongers' shops, evil-smelling from avoidable putrefactive bacteria, are sanctioned, though I presume that under the present Health Acts of the United Kingdom their present condition is illegal. Prior to considering the effects of ice on fish, it is necessary to recollect the previous stages of fish life and fish death, from the time when the fish is caught till it arrives at the consumers.

Accidental injuries.—Wounding with a spear or gaff hook, or by trawling fish in nets over rough grounds, and the pressure of a mass of fish in the nets, cause injuries to the skin, scales, fins, tail, gills, muscles, abdomen, and other parts of the fish, and increase its rapid putrefaction. In the trawl immature fish often get so spoilt and injured that they are technically said "not to take the ice," and are hence thrown back into the sea.

Avoidable fish-spoiling through carelessness, filth, and bad packing.—Placed upon their bellies on the usually filthy boards at the bottom of the smack, the abdomen of fish

Digitized by Google

may rot whilst its sides and back remain comparatively sound. In the United Kingdom captured fish are often thrown *unbled* and *ungutted*, and always unpithed, into the more or less foul hold of the fishing boat, where they remain exposed to successive alternations of heat, sunshine, moist and melting ice, and putrefactive filth. The fish are frequently ruthlessly crushed, bruised, and cut by the heavy weights of their thoughtless captors standing in sharp-nailed boots, whilst the lower layers of fish may have tons of fish resting upon them. In some parts of England, from about September till April, many of the smacks fish by themselves, and not in a fleet, from which a steamer or other carrier takes away each day's fish. As such isolated smacks stay out at sea about a week, it follows that a portion of their catch has been already some six days in ice before landing. Such stale fish by putrefactive contagion damages the fish more recently caught. On reaching the harbour the fish are commonly pressed into filthy fish boxes, barrels, and baskets pregnant with putrefactive bacteria. The fish suffer further shaking, banging, and bruising by being flung about on the pier, where this food lies again exposed to heat, rain, and sunshine. As the fish boxes or trunks have always wide open apertures, and in the carrying boats and railway and street vans the boxes are closely piled one above the other, it follows that the flowing filth from the upper boxes circulates through the lower ones, whilst the last tier both from above and below is surrounded with these putrefactive abominations.

The empty fish trunk weighs from 19 lb. to 28 lb. Its ice and melted ice may be taken at from ½ lb. to 1½ lb. Exclusive of the box or trunk at Billingsgate, a box or trunk of brill is supposed to weigh from 80 lb. to 90 lb. of fish; of gurnards or rays, 70 lb; of hake, 112 lb.; of soles, 70 lb. to 100 lb.; of mackerel, 112 lb.; of plaice, 80 lb. to 100 lb.; and of whiting, 80 lb. The usual size of a fish trunk is 24 in. by 18 in. by 9 in., with a capacity of 2¼ cub. ft., but these trunks are occasionally so packed that from 20 to 40 per cent. dead weight of fish may be wanting. "Taking the load" is a market term alluding to a trade trick of emptying out three trunks, and then repacking the fish so as to make it pass as the contents of four trunks. Trunks or boxes when the fish come up to the top are called "levels," but if the fish be piled up in excess these are termed "fulls." It is said to be a common trade trick to double up a big flat fish in the middle of the trunk to make the load appear full, or else to add 20 to 30 per cent. of ice. *Loose* trunks are those underpacked with fish. Hence it is evident that in the wholesale markets, to a certain extent, fish is sold by guess-work, an element of gambling which Parliament should stop by compelling fish to be sold by accurate weight only. The pound avoirdupois would make the best standard. Of course this gambling in fish is virtually carried on at the expense of the consumer—the public.

Fish are, again, further damaged by close packing and pressure. To economise space in packing the barrels, a sharp sudden wrench or twist bends the fish into a coil, breaking up the animal's softened muscles and structures, thereby inviting and increasing putrefaction. Finally, such fish are tightly crammed into the conventional rough, porous, unvarnished, foul boxes and barrels, which are rudely closed by sharp hammering. Suddenly twisting the tail of the whiting, &c., to pass through its mouth, ruptures the soft, flabby, loose muscular fibres, especially when such fish have been previously skinned. The exposure of dead fish thus wastefully maltreated in fishmongers' shops, pregnant with putrefactive bacteria, accelerates decomposition.

When fish has once become flabby, stale, or tainted, no preservative process can possibly restore its lost flavour, freshness, or firmness. The few fish which British fishermen occasionally gut are often to be seen placed in a few inches of stagnant water, super-saturated with putrid blood and filth. Frequently handling fish, especially with dirty hands, accelerates putrefaction, as also the time-honoured chronic conventional custom of watering fish on the fishmonger's slab. By a statute of Edward I., dated 1272, no fishmonger was allowed to water his fish more than once; no fresh fish was to be kept in London beyond the second day from its capture; nor was any bad fish to be sold. The profit of the London fishmonger was limited by this statute to one penny in the shilling. Of course, in those days neither the fishermen nor the public were afflicted with the middlemen wholesale salesmen, whom it is alleged make undue profits apparently at the expense of the fishermen and of the public.

Fisherfolk so fully realise the present difficulty of preserving fish, that stale and decomposed fish is technically termed "over-day" (over-a-day) fish. Fisherfolk state that thunderstorms spoil fish, but as thunderstorms occur chiefly in hot, still weather associated with rain, the explanation is included in the fact that fish decompose quicker on a wet, windless winter's day than during a dry hot summer's day with a brisk breeze. Others credit the bright rays or a full clear moon with causing rapid decomposition of freshly-caught fish; but here, also, there seems to be no foundation for this statement.

Railways spoil fish.—Suddenly flinging down a heavy fish trunk loosens and damages the soft muscular fibres of fish, accelerating decomposition. Owing to the continued violent shaking in transit, railway-carried fish is so greatly damaged that even its wholesale trade price is lessened by upwards of 25 per cent. when compared with water-borne fish.

Chemicals spoil fresh fish.—Common salt, brine, boracic acid, tartaric acid, nitre, sugar, burning sulphur and aromatics, boro-glyceride, lime-water, shea or vegetable butter, powdered charcoal, flour, sawdust, or other antiseptics, as well as forcing under mechanical pressure chemical solutions into fresh fish, alike fail to keep fish from decomposing when applied in the usual commercial proportions.

Ice spoils fish.—The thickness of fishes and certain qualities of their skin cause slight variations in the freezing point of the different kinds. The freezing point of fish is a few degrees below that of water or of the ordinary commercial ice at 32° F., which, even were it used in large excess, could then only superficially and incompletely chill the exterior layers without practically affecting the temperature of the interior of a thick fish's body. But even in these conditions ice spoils the freshness, firmness, and flavour of fish by rendering it, prior to putrefaction, insipid, soft, and flabby. In the United Kingdom, by coasting vessels, fishing is seldom carried on during Saturday afternoons and all Sunday, fish caught on Friday night and often days previously, especially during continued storms, fogs, and calms, could not reach Billingsgate till Monday morning, and the consumer late on Monday, when it would never be less than three days old and often more. Indeed, much of the best prime trawl-caught fish sold at Billingsgate is from three to ten days old! The London fish trade alone is now (1889) said to consume upwards of 1000 tons daily of ice during the summer months. Ice is an expensive, bulky, rapidly perishable, wasteful product. The present average wholesale winter or minimum price of rough artificial ice is as low as 11*s.* the ton, when purchased in quantities of two tons or more, and the average price of artificial ice in winter bought by the smaller fishmongers and costermongers is 1*s.* the cwt., or at the rate of £1 the ton. In London the price of natural Norwegian ice is, even in winter, often £1 10*s.* the ton, which is popular in Billingsgate and other fish markets, where also actually *crushed* natural ice at 1*s.* 9*d.* the cwt. or £1 15*s.* the ton is customary. Being imported from the metropolis, ice in most fishing districts is, again, much dearer than in London. Compared with the winter prices, during the summer months, when ice is most used and most wasteful, it is much dearer—sometimes by 50 per cent.

Poisoning by iced fish.—Experience seems to show that the gravest cases of fish poisoning arise more commonly from eating fish which has been kept on ice than from eating fish kept naturally cool. Where fish is preserved on ice it appears to me that the ice only favours putrefaction by furnishing a constant supply of moisture, carrying with it the putrefactive bacteria derived from its foul and filthy surroundings, so that this iced fish remains covered with fresh solutions of filth pregnant with putrefactive bacteria. Thus large quantities of those subtle complex bodies, the animal alkaloids or ptomaines, are probably elaborated, and give rise to those marked symptoms of poisoning which sometimes occur from eating fish preserved on ice. On the other hand, keeping fish dry and cool can in no way favour putrefaction. And although here cases of poisoning may happen, yet, as far as I can gather, the symptoms are much less marked, and pass off sooner, the toxic effects being usually confined to a passing attack of vomiting and diarrhœa. Whilst in the case of fish preserved on ice the vomiting and diarrhœa may be less marked, though the other

Digitized by Google

symptoms may be much more profound and lasting, and even sometimes fatal.

There are various poisons derivable from putrid fish, the detailed consideration of which require much further elaboration, work, experiment, and research. Indeed, as upwards of seventy different kinds of food-fishes, within a few hours of their death, on being eaten, give rise to poisonous symptoms, the Russian Government in 1894 will award a prize of 5000 roubles (say roughly £500) for the best essay upon the nature and cure of fish poisoning. It is unwise of Parliament not to imitate and initiate similar plans for the benefit and protection of the British and colonial public, especially for the poor, whose cheap, healthy food-supply seems chronically shamelessly ignored and outrageously neglected by those in official legislative authority. Independently of the sacred duties of charity, humanity, and religion, if viewed exclusively as a matter of public economy and expenditure, as a matter of mere pounds, shillings, and pence, then the question of cheap, healthy, abundant food means diminished taxation, which appeals directly to the pocket of every individual taxpayer. The solution of this subject as regards increasing the supply of fish, whilst lessening its cost and improving its quality and commercial value, I reserve for subsequent communications.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

Experiments by the Jury on Hygiene.—International Congress on Accidents to Workmen.—Exhibits of Waterproofs and Textile Fabrics.

THE time is now rapidly approaching when the distribution of prizes to the exhibitors will take place. I cannot speak of all the classes of the Exhibition, but this much at least may be said—the rewards in all that relates to public health have been fairly, honourably won. The juries have done their work in a thoroughly conscientious and scientific manner, especially with respect to all that relates to filters and to drainage. With regard to the latter, the gentlemen of the jury not only allowed me to be present, but were anxious to avail themselves of any advice I could give. The experience acquired at the International Health Exhibition held in London four years ago was fully utilised and improved upon. The jury had a small hut built immediately behind the Pavilion devoted to the sanitary exhibits on the Place des Invalides, and here the experiments were made, day after day, for several weeks. Each closet-pan submitted was carefully measured, and a drawing to scale taken. Then the pans were in turn affixed to the same flush tanks, so that the conditions of the experiment were equal for all. A flush of ten litres of water was given in every instance—that is, a trifle (a litre) more than our usual two-gallon flush. The pans were first painted with plumbers' ink, and notes taken as to how far the stains were removed by the flush, and whether any of the water splashed over the border of the pan. Then pieces of paper were placed round the pan to see if these were all removed by one flush. Finally a fixed number of potatoes or apples were put into the syphon to test if the flush could remove them all. Careful notes were taken of each experiment, and thus a comparison, based on the material results, was established as to the respective value of each pan, showing whether the pan was thoroughly cleansed and the trap completely emptied by the usual flush. The earthenware drain pipes of which an increasing number are now manufactured in France, were next examined. Every pipe was submitted to four different experiments. To test resistance to external pressure, a long plank of wood was placed over the pipe. One end of the plank was held down to the ground. On the other higher end weights were placed till at last the pipe broke under the increasing pressure. This test showed how greatly the pipes varied in quality; for, while the weakest broke under a weight of 800 kilogrammes, the strongest carried 2500 kilogrammes. The experiment for internal pressure is not so important, as it is very rare that a drain or even a sewer pipe is exposed to very great internal strain. Nevertheless, the experiment was made. Both sides of the pipes were cemented, a little hole remaining at one end to introduce the nozzle of the pneumatic pump. It was then found that the pipes could resist internal pressure of from four to six and a half atmospheres before bursting. The third experiment was particularly useful. It was to see how far a pipe could resist a shock or blow. Where earthenware pipes are used for the drainage of small streets, and are not laid deep, the passing of heavy carts or the fall of heavy loads may cause such pipes to break. The pipe was placed by the side of an upright measured gauge. An iron ball weighing six and a half kilogrammes was raised along this gauge and then allowed to drop upon the pipe. Each time the ball was dropped from a greater height until at last the pipe broke. The result was that the weakest pipe broke when the ball fell from a height of ten centimetres, and the strongest was only broken when the ball was raised to the height of twenty centimetres. The fourth and final experiment was of a very important and ingenious character. The pipes selected measured fifteen centimetres in diameter and sixty-five centimetres in length. They were placed in a heated oven for twelve hours so that they should be thoroughly dried, and then they were carefully weighed. After that the pipes were put to soak in water for twenty-four hours; then taken out and weighed again. The object was to ascertain how much humidity the pipes were capable of absorbing. The difference of the results attained was very remarkable. The best pipe only absorbed 150 grammes of water; the worst took up no less than a litre, or 1000 grammes.

During all the past week a very interesting international Congress has held its sittings at the Ecole de Droit, on the question of accidents to workmen and employers' liability. Some of the debates were purely technical, and only concerned engineers. For instance, the question of boiler explosions and the best means of constructing and placing machinery so as to avoid accidents. Then a great deal was said as to the right of inspection and the duty of inspectors. This, in France, is limited to factories where women and children are employed, the Legislature deeming that adult men are able to take care of themselves. The members of the Congress were for the most part engineers, factory inspectors, delegates of chambers of commerce, a few actuaries—in all more than 700 delegates, including the official representatives of eleven European governments, several members of various parliaments, and a few doctors of law and of medicine. The importance of such a Congress from a public health point of view is perhaps best set forth by glancing at the report on the statistics of accidents to workmen, read by M. Octave Keller, mining engineer, and Vice-President of the Parisian Statistical Society. For instance, the French railway companies, which now employ 223,000 servants, show that the annual average, taken on the experience of the ten years from 1875 to 1884, is equal to 239·5 killed and 1850·4 wounded. In Germany, the average proportion of railway servants killed and wounded is equal to 4·64 per 1000, of which 1·35 are killed. In England the proportion of killed is much higher, being equal, on one railway, from 1882 to 1885, to an average of 2·431 per 1000 employed, and, according to some authorities to 3·3 throughout the country. For coal mines in France, for ten years, the average killed was 1·56 per 1000 and 8·87 per 1000 wounded. But all these figures seem but as details when compared with the magnificent statistics of the German empire. There, to apply the Bismarckian laws on compulsory insurance, a full census of the exact occupation of every person in the empire was taken. Thus in 1887 there were 259,977 State servants and 3,861,560 workmen or artisans insured by their employers in the sixty-two corporations of the various trades concerned. The last year's record shows that 115,000 accidents took place, of which 17,102 were so serious as to entail more than three months' treatment. These latter figures give some idea of the magnitude of the question treated by the Congress, and show how numerous are the accidents to workmen which occur, and will continue to occur unless more stringent measures are taken. Industry, as M. Linder, the President of the Congress, remarked on the opening day, is a battle-field strewn with dead and wounded. We shall never quite succeed in preventing this, but we can reduce the danger and we can relieve the afflicted. The only difficulty with regard to the latter proposal is the fact that if sufficient compensation is guaranteed to the workman in case of accidents, he will become careless, and mishaps will be of more frequent occurrence. Then there is also the danger of simulation of injury. This, however,

Digitized by Google

the Congress did not feel itself very competent to discuss, and the subject had already been very well debated at the Congress on Forensic Medicine.

Another point on which the members of the Congress did not venture at very great length, but on which, however, strong opinions were expressed, related to the diseases engendered by certain trades. The use of black aniline dyes has recently been found to be very dangerous; and there are of course the old enemies—lead, mercury, sizing, cotton and woollen dust, &c. The illnesses and the subsequent deaths caused by injurious occupations are far more frequent, far more disastrous, than accidents of a violent description. Nevertheless the Congress did not venture to make any proposals in this respect, though all felt, and felt strongly, that there was just as much reason to compensate for illness as for accidents. Doubtless, however, the members of the Congress thought that this phase of the question could with more advantage be treated at a Congress of Hygiene or of Forensic Medicine. Several valuable observations were made and figures given showing the exceptional prevalence of accidents to children in factories. These, it was said, were due to the carelessness, thoughtlessness, giddiness, and curiosity of the children. But, on the other hand, it was recognised that these were all the natural characteristics of youthfulness, and only proved that the monotony of factory work was not in keeping with the physical requirements of a young child. The real fault was due to the admission of such young children to the works. Apart from these questions, the Congress devoted the greater part of its time to debating the social, economical, and political consequences of compulsory insurance against sickness and accidents. This involved the examination and the criticism of the recent and sweeping measures taken in this respect by the German Legislature. The arguments for and against are certainly very complex, and the Congress, perhaps wisely, refrained from expressing by vote any opinion. Undoubtedly the German system has a very marked and direct bearing on the health of the population, and would supply the subject of a most useful investigation. Finally, the Congress resolved to form an international society for the purpose of collecting and of exchanging all documents bearing on the question of the prevention of accidents. The annual fee for membership is ten francs, and the address of the International secretary is M. E. Grunner, 6, rue Féron, Paris.

I will now resume my notices of the various exhibits, the continuity of which has been interrupted by the reports of the different Congresses. In a previous letter some of the articles of clothing exhibited were described, but still a great deal remains to be said and seen on this subject. Unfortunately it is not altogether easy to obtain the information which it is the object of an exhibition to supply. For instance, Messrs. Barlow and Jones of Manchester have an immense exhibit. There is a great variety of sheeting that would be of interest as bearing on the bedding of hospitals, and friction towels appertaining to the hygiene of the bath-room; but there is no one to open the case to show specimens or give information. The same cannot be said of Messrs. Robinson and Cleaver of Belfast. Here there are always attendants who lose no opportunity of displaying all the goods. Consequently it was not difficult to ascertain that this firm supplies a large quantity of linen for hospitals. Some of these linens are remarkably cheap, and seem of good quality. They have also some excellent grass-bleached diapers of very soft finish that may be recommended. Close by, Messrs. Haynes and Co. exhibit their well-known absorbent and medicated cotton wools. With regard to woollen fabrics, the exhibits of Messrs. Hunt and Winterbotham of Dursley may be mentioned. Under a rainbow-like array of clothes they show the woollen threads, and then the wool itself employed in manufacture. There is no glass case, everyone can examine the clothes for himself, and, as some of these are supplied for the uniforms of the English army, their quality becomes a question of national importance. Messrs. Tyler and Co.'s case contains unshrinkable flannels, jerseys, and various suits of knitted woollen clothes, which must be recognised as excellent for their porosity and warmth. Messrs. Le Gros Thompson and Son have a weatherproof silk crape that will commend itself to ladies in mourning; but, on inquiry, it appears that the weatherproof quality relates rather to the stains than to the wet which results from rain. Messrs. J. and J. Cash have friction towels and gloves for baths. They differ from most articles of this description, and seem more like a network made of tape. Whether this is or is not more effective, or whether its action on the skin is more stimulating, is a question that must be left in doubt, for there are no means afforded of testing the same. A little circular, with a small specimen attached, renders the patent of Walry's antiseptic canvas intelligible to all comers. This consists simply of a rough loose web-work or canvas well saturated in tar and pine oil. The canvas is then enveloped in two layers of perforated flannel, which is used for underclothing. The theory is that the skin is thus protected by an antiseptic, and also that, as the pores absorb the emanations of the tar, this may have a healing effect in some diseases. Scientific experiments should be organised to demonstrate positively these suggestions.

In the hosiery department, the use of wool for underclothing has greatly increased, and these exhibits show what progress modern theories on sanitary clothing have made. The difficulty is in ascertaining whether articles said to be pure wool are really what they are described to be. Customers cannot carry microscopes in their pockets when they are about to buy a pair of socks. For those (and their number is increasing every day) who want wool, and nothing but wool, a quick and easy method of testing should be devised. Perhaps the easiest test is to separate the warp from the woof, and hold both to a flame. Wool forms into an amorphous mass, leaves a shapeless ash, and does not flame any more when removed from the fire or light. Cotton, on the contrary, continues to burn steadily, and its ash retains the shape of the thread. It would be well for exhibitors to give the fullest information as to the purity of their wools and the absence of poisonous materials in the very brilliant colours they employ. In this scientific age, people, we are glad to note, are not satisfied with mere appearances. It does not suffice if an article of clothing looks well; it must also be free from any deleterious substance.

In respect to waterproofs, also, a great demand has arisen for the better ventilation of these garments. People are commencing to understand that the action of the skin is impeded by wearing an unventilated waterproof, and that the accumulation of foul damp air under the waterproof and the sudden transition produced by its removal, are so contrary to the general scheme of nature as to create greater dangers than the risks involved by getting wet in the rain. Thus almost every exhibitor boasts that he has some special and particularly effective method of ventilating his waterproofs. Messrs. Mandleberg and Co. have, for instance, a number of indiarubber tubes that pass up the back of their coats, these communicating with the outside at the seams. The tube in its course up the back has at every two or three inches' distance a small aperture, and thus these tubes form small ventilating shafts, just where most of the hot air accumulates. How far this is actually successful in practice I cannot say, having witnessed no experiments, but I am tempted to think that the india-rubber tubes are not stiff enough and might close up, if the wearer leant back against a wall or carriage seat. This company, in common with several other exhibitors, shows some very elegant silk and rubber air cushions that only weigh three ounces, and can fold in a little packet three inches square. When blown out they make excellent cushions or head-rests for travelling purposes, and are a very good protection against the vibration of railway trains. The North British Rubber Company has a stand where all kinds of travelling contrivances are exhibited, together with a sort of history of caoutchouc from the tree to the manufactured article. There are innumerable specimens of various forms of goloshes. In this also may be noted the progress of more scientific principles. Formerly the idea of keeping the foot dry was the only thought entertained. Hence the clumsy golosh that covered the whole of the foot up nearly to the ankle. Now, on the contrary, manufacturers are beginning to understand that the idea is to give as little caoutchouc and as much air as possible. Thus it is only the front sole and the seam of the boot that are covered. Under the instep the air may have full play, the heel is unprotected, its thickness is sufficient to resist the water, and under the arch a thin band holds the light golosh that is under the fore part of the foot. Speaking of foot covering,

Messrs. Hubert and Co. exhibit their hunting boots, with indelible coloured tops, which require neither scrubbing nor polishing, and can be cleaned by simply holding under a tap of water. To the lovers of hunting this is a great advantage, and it helps to keep the boot dry. Mr. George Cording, of London, has waterproofs ventilated by placing network under the cape, so that as long as the cape does not adhere too closely to the body there would be no difficulty for the hot air to escape. Messrs. Lee Brothers have a large show of woollen waterproof fabrics, of portable baths, buckets, basins, &c., all objects that would certainly be of interest, alike for medical, hospital, and general sanitary purposes. But their case is always closed; there is no agent or representative to give any explanation. I am puzzled to say what advantage there can be in exhibiting in such a manner that no one can judge the value of the object exhibited. Still, and in spite of such difficulties, there is something to be learnt by a visit to the textile section and the clothing exhibits of the British section.

Paris, Sept. 16th.

THE INFECTIOUS DISEASE (NOTIFICATION) ACT, 1889.

THE following is the text of a circular addressed by the Local Government Board to all district boards and vestries in the metropolis. The circular is accompanied by an order prescribing a form of notification for use by medical practitioners and a memorandum for their guidance.

Local Government Board, Whitehall, Sept. 13th, 1889.

SIR,—I am directed by the Local Government Board to draw the attention of the district boards to the provisions of the Infectious Disease (Notification) Act, 1889, which received the Royal assent on the 30th ult., and which, it is hoped, may materially assist the local authorities of England and Wales in checking the spread of infectious disease, by enabling them to obtain early and accurate information with respect to the cases of infectious disease occurring within their districts.

The Act will, after Oct. 30th, 1889, extend to every London district—that is to say, to the City of London and the several parishes and districts under the jurisdiction of the metropolitan vestries and district boards and the Local Board of Woolwich.

The local authorities for the purposes of the Act will be—in the City of London, the Commissioners of Sewers; in Woolwich, the Local Board of Woolwich; and in the remainder of the metropolis the vestries and district boards acting under the Metropolis Management Acts.

Section 3 of the Act provides that where an inmate of any building used for human habitation within a district to which the Act extends is suffering from an infectious disease to which the Act applies, then, unless such building is a hospital in which persons suffering from an infectious disease are received, the following provisions shall have effect—that is to say: (*a*) The head of the family to which such inmate (in the Act referred to as the patient) belongs, and in his default the nearest relatives of the patient present in the building, or being in attendance on the patient, and, in default of such relatives, every person in charge of or in attendance on the patient, and in default of any such person, the occupier of the building shall, as soon as he becomes aware that the patient is suffering from an infectious disease to which the Act applies, send notice thereof to the medical officer of health of the district. (*b*) Every medical practitioner attending on, or called in to visit the patient, shall forthwith, on becoming aware that the patient is suffering from an infectious disease to which the Act applies, send to the medical officer of health for the district a certificate stating the name of the patient, the situation of the building, and the infectious disease from which, in the opinion of such medical practitioner, the patient is suffering.

Every person required by this section to give a notice or certificate who fails to give the same will be liable on summary conviction in manner provided by the Summary Jurisdiction Acts to a fine not exceeding 40*s*. If, however, a person is not required to give notice in the first instance, but only in default of some other person, he will not be liable to any fine if he satisfies the Court that he had reasonable cause to suppose that the notice had been duly given.

A notice or certificate to be sent to a medical officer of health in pursuance of the above provisions may be sent by being delivered to him, or by being left at his office or residence, or may be sent by post addressed to him at his office or at his residence. Where, in any district of a local authority, there are two or more medical officers of health of the authority, the certificate must be given to such one of them as has charge of the area in which the patient referred to in the certificate is, or to such other of them as the local authority may from time to time direct.

It will be observed that Section 3 refers only to cases where the patient is an inmate of a building used for human habitation. Section 13 of the Act, however, declares that the provisions of the Act shall apply to every ship, vessel, boat, tent, van, shed, or similar structure used for human habitation in like manner, as nearly as may be, as if it were a building, and that a ship, vessel, or boat lying in any river, harbour, or other water not within the district of any local authority within the meaning of the Act, shall be deemed for the purposes of the Act to be within the district of such local authority as may be fixed by the Board, and where no local authority has been fixed, then of the local authority of the district which nearest adjoins the place where such ship, vessel, or boat is lying. This section will not, however, apply to any ship, vessel, or boat belonging to any foreign Government, nor will the Act extend to any building, ship, vessel, boat, tent, van, shed, or similar structure belonging to her Majesty the Queen, or to any inmate thereof.

The expression "occupier," which occurs in Section 3, is defined by Section 16 as including a person having the charge, management, or control of a building, or of the part of a building in which the patient is, and in the case of a house the whole of which is let out in separate tenements, or in the case of a lodging-house, the whole of which is let to lodgers, the person receiving the rent payable by the tenants or lodgers, either on his own account or as the agent of another person, and in the case of a ship, vessel, or boat, the master or other person in charge thereof.

Section 4 of the Act enables the Board from time to time to prescribe forms for the purpose of certificates under the Act, and requires any forms so prescribed to be used in all cases to which they apply.

The Board, in pursuance of this power, have issued an order, a copy of which is enclosed herewith, prescribing the form of certificate required by the Act to be sent to the medical officer of health by the medical practitioner.

The Board also enclose a memorandum for the information of medical practitioners, which they suggest might accompany each supply of forms of certificates.

The Act requires the local authority to gratuitously supply forms of certificate to any medical practitioner residing or practising in their district who applies for the same, and to pay to every medical practitioner for each certificate duly sent by him in accordance with the Act a fee of 2*s*. 6*d*. if the case occurs in his private practice, and of 1*s*. if the case occurs in his practice as medical officer of any public body or institution.

Where a medical practitioner attending on a patient is himself the medical officer of health of the district he will be entitled to the same fee as if he were not such medical officer.

Any expenses incurred by a local authority in the execution of the Act are to be paid as part of the expenses of such authority in the execution of the Acts relating to public health; but the greater part of these expenses, so far as they are incurred in respect of places within the Metropolitan Asylum district, will be recouped to the local authority if the directions of section 10 of the Act are observed, which provides that where a medical officer of health receives, in pursuance of the Act, a certificate of a medical practitioner relating to a patient within that district, he shall within twelve hours after such receipt forward a copy thereof to the managers, and that the managers shall repay to the local authority the amounts paid by the authority in respect of those certificates of which copies have been sent to the managers, as required by that section.

The infectious diseases to which the Act applies will in all cases include the following diseases: Small-pox, cholera, diphtheria, membranous croup, erysipelas, the disease known as scarlatina, or scarlet fever, and the fevers known by any of the following names—Typhus, typhoid, enteric, relapsing, continued, or puerperal. If the local authority of any district to which the Act extends desires that the Act shall in their district apply to any infectious disease other than the above, they may from time to time by resolution order that the Act shall in their district apply to such disease. In such a case, at least fourteen clear days before the meeting at which the resolution is passed is held, special notice of the meeting and of the intention to propose such resolution must be given to every member of the authority. The order embodied in the resolution may be permanent or temporary, and, if temporary, the period during which it is to continue in force must be specified therein, and any such order may be revoked or varied by the local authority by which the order is made. But no such order, or any revocation or variation of it, will be of any validity until approved by the Board.

When it is so approved the local authority must give public notice thereof by advertisement in a local newspaper, and by handbills, and otherwise in such manner as they think sufficient for giving information to all persons interested. They must also send a copy thereof to each registered medical practitioner whom, after due inquiry, they ascertain to be residing or practising in their district.

The order will come into operation at such date not earlier than one week after the publication of the first advertisement of the approved order as the local authority may fix.

In the case of emergency the resolution may be passed at a meeting of which three clear days' notice has been given. In any such case the resolution must declare the cause of the emergency and be for a temporary order, and a copy of the resolution must be forthwith sent to the Board and advertised, after which the order will come into operation at the expiration of one week from the date of the advertisement. But unless approved by the Board it will cease to be in force at the expiration of one month after the resolution is passed, or such earlier date as may be fixed by the Board.

As the Act will take effect in the metropolis on Oct. 30th next, the local authority should, as early as practicable, furnish every medical practitioner residing or practising in their district with the forms of certificate which have been prescribed, and the Board suggests that they should, without delay, take such steps as may appear to them to be most convenient for giving notice of the requirements of the Act to the inhabitants of the district. Judging from the experience of a large number of provincial towns in which provisions similar to those contained in the Act have been put in force by means of local Acts, the Board do not anticipate that the local authority will have any practical difficulty in securing a due compliance with the provisions of the statute, and the Board feel assured that the authority will take such action in connexion with the notifications which they will receive as will materially assist in checking the spread of infectious disease in the metropolis.

I am, Sir, your obedient servant,

HUGH OWEN, Secretary.

ST. THOMAS'S HOSPITAL OLD STUDENTS' DINNER. The annual dinner will take place on Tuesday, Oct. 1st, 1889, at 6 for 6.30, in the Governors' Hall, St. Thomas's Hospital (entrance from Westminster-bridge), Dr. John Harley in the chair.

LITERARY INTELLIGENCE.—Dr. Sakhnovski, Medical Inspector of the province of Kieff, is about to bring out a new monthly journal dealing with epidemics, entitled the *Epidemicheski Listok*.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Epping Rural District.—Mr. T. Fowler gives in a tabular form an account of the cases of infectious diseases that have occurred, together with a statement as to the action taken with regard to each, the latter including, in one instance, successful proceedings against a person for moving a scarlatina patient whilst still in an infectious condition. The drainage of the populous parts of the district has been completed, with the provision of a system of sewerage for Chingford, and a large amount of sanitary work is now regularly carried on for the abatement of nuisances, and for generally improving the health of the district. The sanatorium was useful during the year for the isolation of cases of scarlatina, but its usefulness would be increased by the provision of proper means of disinfection. The death-rate for 1888 was 15·5 per 1000 living.

Tendring Rural District.—The general death-rate for the last year in this district was 16·7 per 1000, and the increase which this represents over the rate for last year is regarded by Dr. J. W. Cook as in part due to excess of deaths amongst infants and young children. There has been a further extension of sewers at Brightlingsea, during the progress of which both enteric fever and diphtheria have diminished, but the privy accommodation in that town is of a very bad and unwholesome sort. Parkeston and Frinton-on-Sea now have good water, but the former place stands much in need of sewerage. Indeed, seaside resorts have been springing up which call for the earnest attention of the authority as regards their efficient sanitation.

Lewes Urban District.—Mr. Braden gives the general death-rate for 1888 as 14·5 per 1000, and points out that the zymotic rate has been but small. He refers to the simultaneous appearance of three cases of enteric fever, each being single attacks in households, and each occurring in widely different parts of the town, and he explains that he could find no cause for them. He evidently inclines to the view that they arose *de novo;* but in the absence of any condition favouring pollution of air or water, it is not clear what the circumstances are which in this case led to the origin of an infectious and specific disease. The need for the proper sewerage of the district known as Cliffe is adverted to; it is a low-lying area, and the culverts show signs of decay. The infectious hospital was found useful during the year, the water-supply is good and plentiful, and good sanitary work goes on week by week.

Kendal Urban District.—Mr. Charles Paget, until recently health officer for Kendal, gives last year's general death-rate as 17·3 per 1000. Midden-privies still cause nuisance in the town, but every year a greater readiness is experienced in getting rid of these structures. Proper construction of house drains, in so far as disconnexion and ventilation are concerned, is enforced in new houses, and a good deal of remedial work is carried out in existing houses where drain defects are discovered. A smart outbreak of diphtheria took place, and with one exception all the cases occurred near a canal in the flattest and lowest lying portion of the town, where a heavy fog had hung about with much persistency. Seven deaths resulted. The merits and value of the Sanatorium were put to the test during the year, with satisfactory results.

Ramsgate Urban District.—On an estimated population of 25,260 the death-rate for 1888 is calculated as 15·5 per 1000, which is lower than any rate during the present decennium; the zymotic rate was also exceptionally low—namely, 1·1 per 1000. Dr. Styan also contends that the deaths from consumption are singularly few amongst the inhabitants, although cases occur amongst strangers. In some cases of diphtheria and enteric fever sanitary defects were found in the houses, the defects being of a sort that would to a large extent have been obviated by a house-to-house inspection, such as is needed, above all things, in health and pleasure resorts. But the limitation in the number of cases of such diseases is regarded as a satisfactory testimonial to the efficacy of the existing sewerage system.

Truro Urban District.—The city of Truro had a low death-rate of 14·0 per 1000 last year, as opposed to an average of 19·67 for the period 1876–87. Mr. Sharp also finds that the occasional cases of enteric fever which occur are not, so often as they were, precursors of serious outbreaks, and this change he attributes to the increased supply of wholesome water and improved drain construction. At the same time improvement is needed as regards the ventilation of the public sewers, and it is important that the question of the ultimate disposal of the sewage should be dealt with. In summer weather the river Kenwyn is in a filthy state, and the stream, or rather the absence of a sufficient stream of water to wash away the filth, is a source of dangerous nuisance, especially to those inhabitants living near its banks.

Hanley Urban District.—It is somewhat difficult to estimate the population of the borough of Hanley, but setting it down as 55,520, the death-rate for 1888 would be 20·7 and the zymotic rate 4·6 per 1000, whilst the mortality under one year of age would be equal to 19·3 per cent. of the registered births, which is certainly excessive. Measles of a severe type accounted for some of this mortality, and school closure, which is stated to have been immediately followed by a diminution in the mortality, had to be resorted to. One case of enteric fever is stated to have been distinctly traced to the milk-supply, the cow-house and premises being in a most deplorable condition. It is, however, not explained in what way the specific pollution was received by the milk, nor whether others besides the one case of enteric fever used the same supply. Isolated cases of enteric fever from milk pollution are, to say the least, extremely rare. The common lodging-houses and the bakehouses seem to be well looked after and to be in a good sanitary condition. The system of compulsory notification of infectious diseases is reported to have worked well, and to have advantages beyond the mere acquiring of knowledge as to the existence of disease in individual houses. Fowler's closets are reported to have been increased in number. As a substitute for privy nuisances they have doubtless effected good, and though we cannot regard them as embodying the principles required in a proper closet, we are glad to note the testimony of Dr. J. S. Walker that they appear to add to the wholesomeness of the localities in which they are placed in Hanley.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5443 births and 3062 deaths were registered during the week ending Sept. 14th. The annual rate of mortality in these towns, which had declined in the preceding four weeks from 19·2 to 16·2 per 1000, rose again last week to 16·7. During the first eleven weeks of the current quarter the death-rate in these towns averaged 18·8 per 1000, and was 1·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 13·2 in Derby, 13·3 in Brighton, 13·4 in Salford, 13·7 in Birkenhead, and 14·2 in Bradford and in Leicester, The rates in the other towns ranged upwards to 26·7 in Blackburn, 27·0 in Halifax, 27·5 in Preston, and 31·4 in Plymouth. The deaths referred to the principal zymotic diseases, which had declined in the preceding four weeks from 811 to 512, rose again last week to 529; they included 272 from diarrhœa, 72 from scarlet fever, 56 from diphtheria, 54 from "fever" (principally enteric), 45 from whooping-cough, 30 from measles, and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Birkenhead and Norwich, and the highest rates in Newcastle-upon-Tyne, Blackburn, Preston, and Plymouth. The greatest mortality from diarrhœa occurred in Plymouth, Hull, Newcastle-upon-Tyne, Blackburn, and Preston; from scarlet fever in Oldham, Huddersfield, Bolton, and Plymouth; from "fever" in Preston and Nottingham; from whooping-cough in Huddersfield; and from measles in Newcastle-upon-Tyne. The deaths from diphtheria included 41 in London, 2 in Manchester, and 2 in Derby. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London

Digitized by Google

Fever Hospitals at the end of the week was 1111, against numbers increasing in the preceding eleven weeks from 559 to 1021; 151 cases were admitted to these hospitals during the week, against 98, 136, and 121 in the previous three weeks. The deaths referred to diseases of the respiratory organs in London, which had been 148 and 142 in the preceding two weeks, rose again last week to 152, but were 48 below the corrected average. The causes of 68, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Bristol, Bradford, Nottingham, and in five other smaller towns; the largest proportion of uncertified deaths were registered in Sheffield, Liverpool, Huddersfield, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·1 and 16·5 per 1000 in the preceding two weeks, rose to 19·1 in the week ending Sept. 14th; this rate exceeded by 2·4 the low rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 12·5 in Paisley and 15·0 in Edinburgh to 22·7 in Aberdeen and 23·6 in Dundee. The 488 deaths in the eight towns showed an increase of 65 upon the number in the previous week, and included 38 which were referred to diarrhœa, 13 to whooping-cough, 11 to "fever" (typhus, enteric, or ill-defined), 9 to measles, 5 to diphtheria, 3 to scarlet fever, and not one to small-pox; in all, 79 deaths resulted from these principal zymotic diseases, against 91, 74, and 66 in the preceding three weeks. These 79 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·2 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 48, 31, and 24 in the preceding three weeks, rose again last week to 38, of which 17 occurred in Glasgow, 8 in Edinburgh, 4 in Dundee, and 4 in Aberdeen. The 13 deaths from whooping-cough showed a further decline of 5 from the numbers in the previous two weeks, and included 6 in Glasgow, 4 in Edinburgh, and 2 in Dundee. The 11 deaths referred to "fever" exceeded the numbers in recent weeks; 4 were returned in Glasgow, 4 in Dundee, and 2 in Edinburgh. The fatal cases of measles, which had been 13, 7, and 3 in the preceding three weeks, rose again last week to 9, of which 5 occurred in Glasgow and 3 in Leith. The 5 deaths from diphtheria were fewer than in recent weeks, and included 2 in Glasgow and 2 in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 55 and 54 in the preceding two weeks, rose last week to 61, but were 14 below the number returned in the corresponding week of last year. The causes of 47, or nearly 10 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·6 and 18·6 per 1000 in the preceding two weeks, rose again to 24·5 in the week ending Sept. 14th. During the first eleven weeks of the current quarter the death-rate in the city averaged 22·8 per 1000, the mean rate during the same period being 16·6 in London and 15·6 in Edinburgh. The 166 deaths in Dublin showed an increase of 40 upon the low number in the previous week; they included 15 which were referred to diarrhœa, 4 to "fever" (typhus, enteric, or ill defined), 1 to scarlet fever, and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 33, 33, and 15 in the preceding three weeks, rose again last week to 20; they were equal to an annual rate of 3·0 per 1000, the rate from the same diseases being 2·1 in London and 3·3 in Edinburgh. The deaths referred to diarrhœa, which had been 26 and 11 in the previous two weeks, rose again last week to 15; and the deaths referred to "fever" also exceeded the number in the previous week. The deaths, both of infants and of elderly persons, exceeded the numbers returned in the previous week. Four inquest cases and 2 deaths from violence were registered; and 36, or nearly a quarter, of the deaths occurred in public institutions. The causes of 35, or more than 21 per cent., of the deaths in the city were not certified.

"Audi alteram partem."

NOTIFICATION OF INFECTIOUS DISEASES.

To the Editors of THE LANCET.

SIRS,—I feel that I must spare a few precious minutes of a very short holiday to make two or three observations on Mr. Biddle's letter to you. He speaks of my "attack," and of my saying "unpleasant things." I think it is altogether the other way, and that it is I who ought to complain. I wrote a short letter to *The Times* in support of Dr. Farquharson's views, and stating my opinion on the subject, an opinion formed after a careful investigation. Mr. Biddle wrote, styling my letter "a very good specimen of its class," and saying that Mr. Ritchie had plenty of such in his pigeon-holes, or words to that effect. I was thus obliged to *defend* my views, and I did so in a letter which *The Times* has evidently considered as conclusive; and this is what Mr. Biddle calls my attack! As to saying "unpleasant things," truths are often unpleasant, and a correspondent who makes remarks in the bad taste—to put it mildly—of those I have quoted above, has no right to expect one to go out of one's way to say things as pleasantly as possible. He complains in his letter to you of my having "misquoted" him, whereas it is obvious from his quotation from my letter that I did not quote him at all (with the exception of seven words), but that I merely summarised his argument, and he does not complain that my summary was an unjust one. Of course, if 1000 deaths from a particular disease in a town are reduced to 950, and in another town 50 are reduced to 0, the same number of lives—viz., 50—are saved in each town; but to argue that the importance of the result is the same is very much like arguing that if one man has £1000 and loses £50 it is of the same importance to him as it is to a man who has £50 and loses all. The relative importance is in each accurately expressed, not by the "difference," as Mr. Biddle contends it should be, but by the "proportion." It is not fair to compare the general death-rates of London and Manchester in an argument about the relative advantages of "single" and "dual" notification, if only on account of the essential difference in their methods of excrement removal; and it is perfectly absurd to suggest that because, for instance, scarlet fever has been epidemic in certain towns where there has been dual notification, this fact is due to the system of notification. The death-rate from diphtheria has increased enormously in London in recent years. This is certainly not due to dual notification. Is it due to the want of it?

I am, Sirs, your obedient servant,

Bexhill, Sept. 17th, 1889. W. H. CORFIELD.

THE MAYBRICK CASE.

To the Editors of THE LANCET.

SIRS,—I regret that my letter on the Maybrick case should have given Dr. Norman Kerr such a shock that amazement would be a trivial expression of his feelings. There is not much to answer in his letter. I do mean that Mr. Maybrick was first dosed with arsenious acid and afterwards with arsenic in solution, but for some two or three days before his death he got no arsenic; that would be another reason why so little was found in the body. Again, I do not think the indictment would be invalid if Mrs. Maybrick had been accused only of administering the poison in solution, and it had been proved to have been given in the solid form. With regard to the large quantity of arsenic found in Mrs. Maybrick's possession, thereby no doubt "hangs a tale" which has not been cleared up. If Mrs. Maybrick knew nothing about it, why did she not indignantly repudiate any knowledge of it when she made her statement? Dr. Norman Kerr's critical mind suggests to him that some member of Mr. Maybrick's family or the nurses may have deposited the arsenic where it was found; if this were so, it could only have been done with a view of inculpating Mrs. Maybrick. What those persons have done to lay themselves open to such a horrible suspicion I quite fail to see. I agree with Dr. Norman Kerr that an intelligent Scotch jury would have probably found a verdict of "Not guilty"; but an equally intelligent English jury had no such opportunity of shirking a responsibility which was

Digitized by Google

thrust on them, and, in accordance with the national character, they boldly did their duty to the best of their ability, and their verdict has been approved by most persons of robust mind and understanding. Again, I agree that the Home Secretary did wisely in giving way to some extent to the clamour of the multitude. In such affairs a crisis will sometimes arise where public opinion seems to lose its head and runs riot with emotion or sentimentality. This sort of agitation cannot be altogether disregarded either in politics or otherwise. The Tichborne case was one in point, the Lipski case another, and now the Maybrick case has run its course; but I venture to predict that if the position of the present Home Secretary be as permanent as the position of Dr. Norman Kerr is stated to be in his letter, the latter gentleman will have to wait a very long time before his desire is gratified—viz., that the prison door be open to Mrs. Maybrick.—Yours obediently,

The Sanctuary, S.W., Sept. 18th, 1889. THOMAS BOND.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to correct an error in Mr. Allen's letter of the 14th. He states: "Mrs. Maybrick added a *white* powder to the meat extract." I have her statement before me, and she never said anything about *white* powder. This was an addition by the press. What she did say was: "When I found the *powder* I took it to the inner room, and in pushing through the door I upset the bottle," &c. The importance of pointing out what may appear to some a trivial matter is this. Some people think that if it was a white powder it was of necessity arsenic. Now, as Mr. Allen himself points out, if this powder was arsenic it would have remained undissolved. We are then positively certain that this powder was *not* arsenic, and that therefore the admission of evidence to this end was with no other object than to blind the jury to the real issue. Your correspondent suggests that Mrs. Maybrick attempted to filter arsenic mixed with soot through a handkerchief. It is monstrous to assert that this woman had any technical knowledge of filtration, however crude, and it is just such misconceptions which have placed her where she is. The prosecution relied on three things for a proof of administration of arsenic: (1) the presence of 1 gr. of arsenic in meat juice, which the deceased never had; (2) the presence of $\frac{1}{1000}$ gr. in a pan at his office, which he never used; and (3) the presence of $\frac{2}{3}$ gr. of arsenic in a glycerine bottle. Siebold (editor of the *Pharmaceutical Report*), at a meeting of the British Pharmaceutical Association held at Newcastle last week, proved that glycerine abstracts As_2O_3 from certain manufactured glass after long standing. This is an important statement, and I must refer your readers to his paper. As to Mrs. Maybrick's guilt or innocence I do not express any opinion; but I do say that in a case involving so many medical, legal, and analytical doubts the only course is to liberate her, and if there is any fresh evidence against her, to re-arrest and re-try her, and not let her be unconstitutionally sentenced for a crime—"attempt to murder"—which was not before the Court.

I am, Sirs, yours truly,

W. H. COATES, M.B., L.S.Sc., F.C.S., M.R.C.S.

Highgate, Sept. 17th, 1889.

To the Editors of THE LANCET.

SIRS,—Your correspondent, Dr. Kerr, in the parallel which he has drawn between the case of Mrs. Maybrick and that of Madeleine Smith, and his inference that the same "intelligent" jury which acquitted the latter would also have done so with the former, overlooks or ignores an important distinction between the two cases. In Madeleine Smith's case there was a doubt as to whether she had administered the poison at all or not; while in the other case neither the Home Secretary nor the jury had the shadow of a doubt on this head. This, I believe, accounts for the different verdict in the two cases. I do not mean to enter into the merits of the recent case—everyone has already had ample means of forming a judgment on the subject. I would only say that I think the Liverpool jury, being convinced that the prisoner had administered poison with intent to kill, did well in holding her responsible for the fatal event which followed, all medical cavilling to the contrary notwithstanding. If a Scotch jury had not done the same in similar circumstances they would have shown little claim to be possessed of that intelligence with which your corresnpodent credits them.—Yours truly,

Partick, Glasgow, Sept. 16th, 1889. ROBERT KIRK, M.D.

"FIVE RECENT CASES ILLUSTRATIVE OF CEREBRAL SURGERY."

To the Editors of THE LANCET.

SIRS,—Under the above heading there is a case (No. 1) recorded in your issue of Sept. 14th which is rather remarkable for its rarity, particularly as complete recovery took place, notwithstanding a bullet remaining lodged in the cranial cavity. With your permission, I will state a case, which has never been recorded, and which I think is most remarkable and unexplainable—to me, at all events. To your readers I shall leave the explanation, hoping that each one may satisfy himself.

Eighteen months ago I was summoned in great haste to the house of a farmer, whose child, I was informed, had been accidentally shot by his brother. I went, and saw the boy—aged about nine years—within a quarter of an hour of the occurrence. His condition was this. He lay on his left side, with his head bent, his chin touching his chest, his legs drawn up and flexed on the thighs, which were touching the abdomen; his breathing was slow, laboured, and slightly stertorous; pulse 50; temperature normal. He was quite unconscious, and I could not rouse him till at the expiration of about twenty minutes, when, on speaking loudly to him and slightly shaking him, he muttered something in great irritation and relapsed into his former state. His right eye was cleanly knocked out, the eyelids a little black and swollen, and immediately over the malar bone of the same side there was a swelling about the size of a pullet's egg. Having observed his condition, as previously described, I obtained the history of the accident, as follows. Four of the children, ranging in ages from twelve to four, happened, while playing in the bedroom, to find a revolver loaded in all its chambers. The oldest child took it to examine, and in doing so, one of the chambers accidentally went off. The other brother—the subject of this case—happened to be standing within a yard and opposite to him, and immediately fell, remaining there in the condition I have previously described as finding him in. Thinking the case was hopeless, I said so, but at the same time sent for my principal, a man of large experience and great tact. When he arrived, he examined the child, as I had previously done, and he came to the conclusion that the bullet must have penetrated the skull through the optic foramen, in the track of the optic nerve, and no doubt was lodged in the brain—where, we could not think. I had previously examined the room where the accident took place, hoping that the bullet might have impinged against some irregularity in the orbital cavity, made a sort of irregular curve, destroying the eyeball, and coming out again, and therefore not entering the cranial cavity at all. On examining the orbital cavity with my finger I could find no irregularity whatever either on the floor, roof, or either side, but could feel the pulsation of the vessels at the foramen lacerum anticum. My principal said that we must not interfere, but wait to see if the boy would rally, firmly believing that it was only a matter of a few hours at most with him to live. After waiting for three hours the boy became sick and vomited some food which he had partaken of some short time previously, and, having vomited, he sat up, looked with his one eye, dazed, and called for a cup of tea. This he had, and after having taken it he commenced to chat and talk as if nothing had happened. We put him to bed, but having left the place I learned afterwards that he would not stay there, but got up and walked about, and did as the other children. Though he was seen twice a day, his temperature carefully taken, and all the other usual symptoms watched for, the result was negative. Not the slightest fever, no pain, no loss of appetite, no headache, no more vomiting, motions and urine passed regularly and normal, was the result day after day from that time up to now. Even with the eye being made a pulp of, one would expect some little fever and constitutional disturbance, but there was not a trace of either. The swelling over the malar bone went down in less than twenty-four hours, and the eyelids, which were not even scratched, had regained their normal colour in a few days, and with the exception of a slight discharge from the cavity of the orbit, which continued for a week, the boy was practically well in three hours after receiving his injuries. That the bullet entered the cranial cavity I have not the slightest doubt, but where it can have lodged without producing even headache, much less paralysis or any of the other well-marked signs of brain irritation, I must leave, like your corre-

Digitized by Google

spondent, to Ferrier, Horsley, or Macewen, hoping that they or some one of your numerous readers might be able to throw some light on, to me, an inexplicable case.

I may add that there was no bleeding whatever. A bullet taken from one of the other chambers was conical in shape, and its greatest diameter was less than a quarter of an inch. On discharging one of the chambers at three yards' distance, the bullet went almost through a quarter-inch board.

I am, Sirs, yours truly,

Osnaburgh-st., Regent's Park. J. J. CLARKE, L.S.A., &c.

A SERIES OF CASES OF PUERPERAL FEVER.

To the Editors of THE LANCET.

SIRS,—On July 24th of this year a midwife attended an ordinary confinement; the woman died a few days after. On July 30th she was called to another, and found the woman lying on the floor confined. She removed the after-birth, and the woman died on Aug. 2nd. An inquest was held, preceded by a post-mortem, and the death certified as "puerperal fever." On the 7th she was called to another, examined her, and after a while, saying that the case was a difficult one, sent for a medical man, who delivered the patient, and she died a few days after of puerperal fever. On the 14th another case was attended by her, which also ended fatally a few days after. On Sept. 8th another confinement occurred in the top room of her own house. She was with the patient—her own daughter—for an hour before sending for another woman (her sister) to act. The midwife did not actually accouche her daughter, but her daughter died of puerperal fever on the 13th.

The connexion between these cases is so obvious that I think it calls for no remark from me, but the following fact may throw some light upon the cause of the first case. The midwife was suffering from specific disease in the tertiary stage, and about the 28th of July had a large piece of loose necrosed bone—the stench from which was abominable—removed from the roof of her mouth. This bone had been exposed for at least a month. Had she been fidgetting this piece of bone about with her finger, and conveyed septic material to her patient?

I am, Sirs, yours faithfully,

RUSSELL M. TALBOT,

Bow-road, Sept. 1889. Medical Officer of Health, Bow and Bromley.

DIPHTHERIA AND ITS TREATMENT.

To the Editors of THE LANCET.

SIRS,—In your issue of Aug. 24th, I find that Dr. Henderson expresses himself as not satisfied with my paper upon the Eliminative Treatment of Diphtheria, in not being sufficiently effectual for the entire expulsion of all the microbes supposed to be attached to the mucous membrane of the gastro-intestinal tract; for he states that in my commencing the treatment by "administering an emetic, followed by an aperient," he fails to comprehend "how a single evacuation of their contents can be of any service at all." It is evident that he has failed to grasp the general view which my treatment is calculated to effect; he should understand that the mustard emetic is not only an effectual evacuant, but it is likewise an excellent germicide. Again, I suggested that this be followed in due course by two doses of the liquor hyd. perchloridi in strong peppermint-water, which is acknowledged to be a most decided germicide as well as a specific alterative and aperient; this is to be followed by a dose of castor-oil. This treatment will effectually destroy and remove the microbes and their spores from the stomach, œsophagus, and fauces, as well as the intestinal tract. I quite approve of the application of his solution of corrosive sublimate; it is one of the remedies I recommended in a former paper; and, with the exception of two or three cases, I was satisfied with the throat application once a day, as being all-sufficient. Dr. Henderson tells us he is attached to the Birmingham Children's Hospital, which would enable him to watch more closely than one could possibly do in private practice.

I regret to learn that he does not agree with me that "tonics and stimulants in the early stage should not be given." In my letter to THE LANCET of November, 1880, I endeavoured to show what unfortunate results followed upon the tonic and stimulating plan adopted in the April of that year in one of the largest London hospitals. Five cases are carefully recorded in your journal—viz., four children, who succumbed under the above treatment within three days; and a probationer aged thirty-three, who had been in her usual good health, but had been in attendance for two days upon two of the fatal cases of diphtheria; she was taken ill with sore-throat on the evening of April 23rd, and in three days she died under similar tonic and stimulating treatment, aided by most assiduous attention from the physicians. I was in hope that this report would have proved a lesson to the profession to withhold such treatment, which doubtless it did with those who perused my paper at the time, although I believe there are many practitioners who still hold to this unscientific and unsuccessful plan of treatment.

When in general practice in Tottenham for several years, I had upon an average half a dozen cases annually to treat, the locality being rather low and damp. I attributed these cases at that time to aerial infection, through a fungus floating in the atmosphere depositing itself upon the tonsils and soft palate, which I at once attacked with a strong solution of nitrate of silver (one drachm to the ounce), and with a camel's-hair brush removed as much as the patient could tolerate, and at each subsequent visit, until the whole was removed. Finding there was a febrile condition present with nausea in many cases, I commenced with a dose of calomel and an aperient, for I found the secretions in a vitiated state; this was succeeded by salines, diaphoretics, and diuretics, in order to aid nature in eliminating the *materies morbi* from the system under which it appeared to be so oppressed and distressed. With this plan of treatment, the patients, being supported with nutritious and unstimulating diet, gradually improved towards convalescence. *Ergo*, for many years I used to look upon diphtheria as a curable disease if called in tolerably early to arrest its progress.

In order to prove the success the above treatment has met with in my hands, having lost but two cases during thirty-five years of active practice, the registrar's book of Tottenham can show but one death from diphtheria as attended by me, and one at Dalston. In each of these cases the delicate children had been ill two or three days before I was called in, when I found the disease had travelled into the windpipe.

I am, Sirs, yours faithfully,

EMANUEL MAY, M.D., M.R.C.P.Lond.

Fairholme, Hanwell, Sept. 2nd, 1889.

PREVENTION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—Dr. F. P. Atkinson's suggestion—and I see from a letter in to-day's *Times* from Mr. Wootton Isaacson, M.P., that the latter purposes to legislate on much the same lines—is excellent as far as it goes. But it would fail entirely unless some better provision were made than exists at present to ensure the competence of the certifier. As the holder of a "recognised public health diploma" myself, I do not claim to *thoroughly* understand the practical details of the Builders Act, nor do I think that members of our profession ought to be called upon to test the soundness of drains or the perfection of connexion and disconnexion. What we want is a class of practical sanitary experts, whose competence shall be guaranteed by a sound theoretical and practical examination—men who should hold a middle position between the medical sanitarian and the engineer, and of such social position as to ensure them against all possible suspicion of being subject to undue influence of any kind. The examination should be enforced by law. It is no more right that an uneducated man (such as are many of the surveyors employed by local boards and analogous bodies) should be permitted to endanger the lives of the public than that lawyers and doctors should be allowed to practise without qualifications.

I am, Sirs, yours faithfully,

C. H. ALLFREY, M.D., F.R.C.S., D.P.H.Camb.

St. Mary Cray, Sept. 4th, 1889.

CASE OF TETANUS OCCURRING TEN DAYS AFTER DELIVERY.

To the Editors of THE LANCET.

SIRS,—I have been very much impressed, on reading the above remarkable case in THE LANCET of August 17th, by Mr. Henry Peacock of Gloucester, as I have not seen

Digitized by Google

a case mentioned in any obstetric work. Although it is quite possible to have been traumatic tetanus, still I am more inclined to the opinion that it was a true case of idiopathic tetanus, induced by insanitary surroundings, more especially when puerperal disease had been prevalent in the neighbourhood for some months previously. If Mr. Peacock traced each one of these puerperal cases to its proximate cause he would find the same results. I have seen a case of idiopathic tetanus in one of the lower animals (a mare of my own) induced by a deplorably defective sanitary condition of my stable, &c. My groom had a little boy who was in the habit of carrying sugar to the manger both before and during the mare's illness, who thus contracted blood poisoning. Singular to say, death resulted in both cases about the same time. I am sure you will agree with me that there should be a thorough and searching investigation into the sanitary condition of Gloucester, as I am convinced that the houses must be in a most unwholesome state. I am, Sirs, yours obediently,

Whitby, Aug. 22nd, 1889. JOHNSON HERBERT.

LUNACY CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—My attention has been called to the following sentence in a leading article in THE LANCET of June 15th, 1889, dealing with an address by Dr. Cosby Morgan at the late Inter-Colonial Conference at Melbourne: "The Lunacy Act is supposed, by its interpretation clause, to require that medical men certifying be properly qualified, but Dr. Morgan has recently seen a case in which the certificate was signed by an unqualified medical man, 'being also a justice and a coroner.'" The inference is that a patient was admitted into a hospital for the insane on such a certificate, and this I am quite sure my friend Dr. Morgan did not intend. Unqualified practitioners have in two or three cases within my knowledge signed lunacy certificates in this colony (I believe such a thing is not unknown in England), but I can vouch for it that these certificates have been as promptly rejected here as they have been in the old country, and that the Lunacy Act which does not compare unfavourably with that in force in England is strictly administered by the officers charged with the duty.

I am, Sirs, your obedient servant,

F. NORTON MANNING, M.D.,
Inspector-General of the Insane and Medical Adviser to the Government.

Gladesville, N.S.W., July 25th, 1889.

"HINTS TO STUDENTS BEGINNING."

To the Editors of THE LANCET.

SIRS,—I am glad to note that others agree with my advice in the Students' Number. Dr. Theodore Maxwell and myself are quite at one as to its being the *general practitioner* with whom the student ought to reside from the outset of study. With the exception of a few localities throughout the English-speaking world, the word *physician* is synonymous with *general practitioner*, and it is of course in that sense I used it. The student residing with a physician in general practice can be assisted with his studies, learn all the routine duties, see cases outside which illustrate and enable him rightly to understand class lectures and theory in books, and lays the foundation for splendid moral qualities—e.g., self-reliance, presence of mind, &c.,—which assistance at post-partum and other serious cases evoke. Besides, the present faulty curriculum gives no true and complete picture to the beginner of his future work, except in a very partial manner during the *last* year. So, after spending much time, money, and trouble, the student finds it too late to retire from medicine if the profession is uncongenial; whereas residence with the practitioner gives him from the commencement some experience of night work, midwifery, infantile convulsions, book-keeping, &c., and if the duties are distasteful he can withdraw at the end of his first session. If the student really wishes to learn his profession, he must work with, and alongside of, his principal.—Yours faithfully,

Sept. 18th, 1889. EXPERENTIA DOCET.

UNIVERSITY COLLEGE, DUNDEE.—The sum of £9000 has been subscribed towards the £15,000 required to found a chair of Physiology in this College.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The British Association.

THE visit of the British Association to Newcastle has been on the whole a success. It is true that numerically it hardly comes up to the expectations of some of its most sanguine promoters, but, on the other hand, its general interest or attendance at the sections has been rarely exceeded. It is as well to mention that the handsome baronial chair used for the first time by Professor Flower on assuming the presidency was a gift of Professor Philipson to the College of Medicine. The carving is elaborate, and was the work of a local artist of high repute, Mr. Elijah Copland. Saturday last saw a very large number of visitors off to Durham where a convocation was held and degrees were conferred, amongst others, on Professor Flower, Professor J. S. Burdon Sanderson, and Professor Turner. The various works in this city and vicinity received a due share of attention, but I believe the great manufacturing works of Armstrong, Mitchell, and Co., Elswick, were viewed by no less than 250 visitors. Among the excursions, Wallington, the seat of the Trevelyans, appeared to be one of the most popular. Wallington has been long famed for its warmth of hospitality, and, indeed, this feature has passed into song and tradition. Leland calls Wallington "the chefist house of the Fenwicks," who lived there until 1689, in great splendour and hospitality. "Show us the way to Wallington," was once a popular air with the Northumbrian pipers. It is strange how old customs survive now we have the philosophers of the "wise week" making all haste to Wallington, as prudent travellers did centuries ago. I cannot leave the Association meeting without alluding to the handsome accommodation afforded in the way of reception rooms by the College of Medicine here. This very fine new building was placed at the disposal of the Association, and was admirably adapted to its purpose, every want of visitors being amply provided for. The College itself is to be formally opened and devoted to its legitimate purposes on Oct. 2nd. A long list of invitations has been issued, and it is to be hoped that the College will have a prosperous career worthy of its noble building.

Newcastle Hospital Sunday Fund.

The annual meeting of the Newcastle Hospital Sunday Fund has been held. It appears that there has been a decrease in the church collections, but an increase in the workmen's fund, which for the first time exceeds the amount collected at the churches; the works collection being £1961 and the church £1956. The number of letters distributed last year was 6280. The total amount of money collected through the fund since its commencement in 1870 had been £63,000, while in the same period 70,000 letters had been distributed.

Stockton.

Last week an interesting ceremony was witnessed in Baldersdale in connexion with the second of the three reservoirs to be constructed for the water-supply of Stockton and Middlesbrough and the surrounding towns. The Mayor of Stockton cut the first sod of this great reservoir. The first reservoir, the Hury, which is rapidly approaching completion, will have a storage capacity of from 800 to 900 million gallons; the second, in Blackton, will hold 460 million gallons; and the third, the Grassholme, which is a compensating reservoir, will contain 1,300,000 gallons. A vast expense is being incurred in this important water undertaking; but the increasing population of the Teeside towns, and the water required for domestic and manufacturing purposes, have left the local water board no other course but that which has been adopted. The site of the new reservoir is in Teesdale, not far from Cotherstone, in the midst of some of the very finest gathering grounds.—The Stockton Dispensary appears, from the account presented at the annual meeting, to be in a waning condition; its income is said to be gradually decreasing from the death of old subscribers. The increase of clubs to which workmen subscribe will also affect this, like many other local charities.

Newcastle-on-Tyne, Sept. 18th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Reformatory and Industrial Schools, Ireland.

FROM the 37th report of the inspector it appears that there was no outbreak of contagious disease in any of the nine reformatories during the past year, and only five deaths amongst an average of 853 inmates, or about six per 1000, which must be regarded as favourable when contrasted with the general death-rate of the ordinary population. In the industrial schools the health of the inmates generally was good, but as these children are younger and come from a more destitute class than those sent to reformatories, the neglect experienced prior to committal make them more susceptible to disease. The only extensive outbreak of disease amongst the children of the industrial schools was at Booterstown, county Dublin, where fifty-eight of the inmates were attacked by typhus fever, and two deaths took place. Scarlatina broke out in several of the schools (eight), but no death took place. The deaths in industrial schools were chiefly the result of scrofula in its various phases; 51 were due to lung disease, 12 to brain affections, and 5 to mesenteric and bowel disease. The total deaths numbered 74, being at the rate of 9 per 1000. The diseases which the inspector (Dr. Plunkett O'Farrell) found most prevalent among the school children were ophthalmia, ringworm, and chilblains during the winter and spring months. The only way of checking purulent ophthalmia in schools is by constant medical inspection, minute attention to the lavatory arrangements, and a complete isolation of all acute cases; while among the hygienic measures nothing is so useful as the provision of a grass plot for play in dry weather. The dietary scale in the greater number of schools, the inspector states, was fairly liberal, but in many schools the quantity of new milk allowed fell short of what was required to build up the constitutions of the young.

The Dublin Barracks.

Some cases of sickness have recently occurred in Island Bridge Barracks, which at present is overcrowded, owing to the 5th Dragoon Guards having been sent there from the Royal Barracks. The Royal Dublin Society have offered their extensive premises at Ball's Bridge for the occupation of troops, in case the sanitary improvements in the Royal and the Richmond Barracks are not finished before the troops have to leave their camp in the Phœnix Park. The two regiments now under canvas there are very comfortable and appear to enjoy themselves very well, but it must be added that the weather of late has been greatly in their favour. So far as I can learn, there has been little or no sickness, and the men do not complain of their sojourn under canvas. Extensive alterations are being carried on at the Royal Barracks, so as to prevent the recurrence of fever and other zymotic affections; and the Royal and Palatine squares are now undergoing a thorough overhauling. As it was found that the quadrangular form of the buildings prevented free ventilation, portions of the buildings at the several angles have been removed, so as to allow fresh air to circulate; while in Palatine-square three of the angles have been taken down. Ventilators have been fixed in most of the rooms in the officers' quarters in this square—in fact, in all the rooms where an outbreak of fever has occurred,—and new flooring put down in a number of the rooms, louvre ventilators being placed at the top of each staircase so as to give thorough ventilation; while the ordinary paving setts in the stables have been replaced by concrete, and new concrete channel courses substituted for the old brick courses. The old prison, which has not been used for years, has also been demolished, and also the riding-school at the rear of Royal-square. It is not expected that the necessary alterations will be finished before next year.

Death of Dr. Henry Coulton.

This gentleman died at his residence in Dublin on the 16th inst., after a somewhat tedious illness, of paralysis. He acted for many years as medical officer in connexion with the South Dublin Union, and retired on a pension about ten years since. He was attended in his last illness by his old friend Mr. Kellock Barton, senior surgeon to the Adelaide Hospital, who was unremitting in his attentions to the deceased. Dr. Coulton was of a kind and amiable disposition, a true friend, and a Christian gentleman.

Health of Ireland for 1888.

The births numbered 109,557 and the deaths 85,892, both being under the average for the previous ten years. The excess of births over deaths was 23,665, but as the loss by emigration amounted to 78,684, there would appear to have been a decrease of 55,019 in the population during the year. As regards the 109,557 births, the rate afforded in proportion to the estimated population was 1 in 43·6, or 22·9 per 1000, which is 1·12 under the low average rate for the ten years 1878–87, and less than the rate in any of those years. The average percentage of the illegitimate births was 2·9, which compares favourably with the returns for most other countries. The registered deaths amounted to 85,892, being equal to 1 in 55·6, or 18·0 per 1000, which is somewhat under the average rate (18·4) for the previous ten years. The deaths of infants under one year old numbered 10,619, being equal to 9·7 per cent. of the number of births registered; while among children under five years of age 19,095 deaths occurred, a mortality equal to 35·9 in every 1000 of the living at that age. It will be seen from these figures that the rate of mortality among children still remains very high.

Zymotic Diseases in Dublin.

During the past three months the deaths from scarlatina numbered only 2, typhus fever 3, measles 30, and typhoid fever 33—returns which must be regarded as satisfactory when contrasted with previous quarters.

The Lord Justices have sanctioned the expenditure of £1600 upon improvements in the Ballinasloe District Lunatic Asylum.

The election of an assistant surgeon for St. Vincent's Hospital will take place on the 23rd inst.

Dublin, Sept. 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Population in France in 1888.

SOME remarkable figures have recently been placed officially before the public bearing on this question. For Frenchmen especially the question is ever an important one, and, touching so nearly as it does on the future position of France in the march of nations, the publishing of these figures showing the state of affairs has excited a considerable amount of attention and comment. Some take a gloomy view of the outlook, and go so far as to declare that France is "within measurable distance" of assuming a third- or fourth-rate place in the rank of nations; while others, on the other hand, declare that the figures only indicate that France will be the first to reach the summit in the climb which all nationalities are making towards a perfected civilisation, and that the turn of the others will arrive later on. France, it is pointed out, is not a colonising nation, and cannot with comfort support much more than forty millions. But no more can Germany or England, who, not without much misery and difficulty, find an outlet for their surplus population in emigration and colonisation, and emigration means merging into other nations, while even colonisation ends in the setting up of new nationalities, with destinies of their own to work out, and little in common with the mother country, unless it be the language. Comfort is taken in the belief that the days of gigantic empires are at an end, and that even "Imperial Federation," so dear to many of your countrymen, is a myth. But whatever side may be taken eventually in this political economists' discussion, there is no doubt that the figures, as published, are interesting reading to medical men. According to the return, the increase of births over deaths in 1888 amounted to 44,772, whereas in 1887 the increase was 56,536. This is certainly a striking falling off, and it is easy to see that at this rate the time is not far off when the quantity will become a *minus* instead of a *plus* one, and those who aim at the "perfected civilisation" scheme must see the necessity of arresting this downward progress if France is to remain numerically a great power. How it may be possible to arrest it is of course another matter. The number of marriages in the year 1888 were 276,848, divorces 4708, births 882,639, and deaths 837,867. As regards marriages, there were 212 less than in 1887, but as compared with 1886 the diminution was much more marked, amounting to no less than 6360. In 1888 there were granted 1072 more divorces than in 1887,

Digitized by Google

and 1758 more than in 1886. Taking France generally, there was one divorce in every 1585 existing marriages; but in the Department of the Seine alone there was one divorce in every 419 homes. The total number of births was 16,794 less than 1887. This is the greatest diminution since 1871. Nor does the diminution show much sign of lessening, if one may judge by the following figures. In 1885 there were 13,200 less births than in the preceding year; in 1886, 11,720 less than in 1885; in 1887, 13,505 less than in 1886. On the other hand, the number of illegitimate births go on increasing. There were 7·5 per cent. in 1881, 8 per cent. in 1885, and 8·5 per cent. in 1888. In the Department of the Seine, of every 100 children born in 1888, 25 were illegitimate; while in Brittany they only amounted to 2 per cent. The deaths in 1888 amounted for France generally to 21·9 for every 1000 persons. The departments returning the greatest birth-rate also show the greatest death-rate, the mortality being most marked amongst infants of tender age.

Ocular Massage.

A communication was recently made to the Academy of Medicine on this rather novel, or, as it would appear, modification of the ancient, use of massage by M. Costomiris of Athens. He said that if the ancient Greeks employed massage in eye affections it was not by means of the pulp of the finger on the conjunctiva and cornea, such as he had been in the habit of employing for many years. His method was, after everting the lids, to spread a thickish layer of fine boracic acid powder on the conjunctiva, and then with one of the fingers to rub in massage fashion the parts so covered with the powder. He then washes the eye in boracic acid solution, and for the few following days applies a lotion composed of 1 in 200 of nitrate of silver to prevent the inflammation which sometimes follows the manipulation. He next rubs the outer surface of the lids in the same way, which he finds lessens any pain caused by the internal massage. It is as well in every case to begin with a short and very light friction, then to increase it and again decrease it, and this should be repeated once daily and continued for two or three weeks after cure. M. Costomiris speaks very highly of this method in the treatment of granular lids or follicular conjunctivitis, in parenchymatous keratitis, in hypopyon, in infiltrations, and in abscesses or ulcers of the cornea; but in deep-seated ocular mischief he cannot recommend it.

Paris, Sept. 17th.

THE SERVICES.

ARMY MEDICAL STAFF. — Surgeon-Major Ignatius McDonogh O'Farrell, F.R.C.S. Ireland, to be Brigade Surgeon, ranking as Lieutenant-Colonel, vice C. S. Wills, C.B., granted retired pay (dated Aug. 24th, 1889); Surgeon William Parsons Feltham, from half pay, to be Surgeon, in succession to Surgeon-Major J. A. Smith, deceased (dated Aug. 15th, 1889).

ARMY MEDICAL SCHOOL. — Deputy Surgeon-General Henry Cayley, Bengal Medical Establishment (retired), to be Professor of Clinical and Military Medicine (dated June 4th, 1889).

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon-Major Burford Norman, having resigned his commission in the 1st Volunteer Brigade, Southern Division Royal Artillery, ceases to be an Officer of the Reserve (dated Sept. 18th, 1889); Surgeon John Alexander Mackenzie, M.B., resigns his commission (dated Sept. 18th, 1889); Surgeon Robert Balfour Graham, F.R.C.S. Edin., 1st Fifeshire Artillery Volunteer Corps, to be Surgeon, ranking as Captain (dated Sept. 18th, 1889).

INDIA OFFICE.—The Queen has approved of the following promotion among the Officers of the Staff Corps and Indian Military Forces made by the Governments in India (dated Sept. 17th, 1889):—Bengal Medical Establishment—Surgeon-Major Henry Black Purves to be Brigade Surgeon (dated June 16th, 1889).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Stephen Sweetnam has been placed on the Retired List at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Sept. 10th, 1889).

The following appointments have been made:—Surgeons George Welch to the *Defiance*, additional for temporary service, Jeremiah Sugrue, to Haslar Hospital, and William G. Stott, M.B., to the *St. Vincent* (all dated Sept. 19th, 1889); Fleet Surgeon Samuel Bamfield to the *Durham;* Staff Surgeon Herbert E. Marsh to the *Serapis;* Staff Surgeon Edward R. Mulock to the *Assistance;* and Staff Surgeon William M. Rae to the *Brilliant*, temporarily (dated Sept. 26th, 1889).

VOLUNTEER CORPS. — *Artillery:* 1st Inverness-shire: Second Lieutenant H. W. Mann, M.B., is appointed Acting Surgeon (dated Sept. 14th, 1889).—*Rifle:* 3rd Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry): Acting Surgeon J. A. Bright resigns his appointment; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated Sept. 14th, 1889).—2nd (Berwickshire) Volunteer Battalion, the King's Own Scottish Borderers: David Skinner, Gent., to be Acting Surgeon (dated Sept. 14th, 1889).—2nd Volunteer Battalion, the Duke of Cornwall's Light Infantry: Acting Surgeon F. D. S. McMahon resigns his appointment (dated Sept. 14th, 1889).—3rd Volunteer Battalion, the Hampshire Regiment: Captain C. S. Ticehurst is appointed Acting Surgeon (dated Sept. 14th, 1889).—2nd Volunteer Battalion, the King's (Shropshire Light Infantry): Acting Surgeon C. H. Gynn, M.D., to be Surgeon (dated Sept. 14th, 1889).

Obituary.

JOHN F. GILLIES, M.D., L.R.C.S.

THE above-named gentleman died at Dunedin, New Zealand, on July 5th, after a lingering illness. He was born in the island of Skye in 1847. As a student in Edinburgh and Aberdeen he gained the highest distinction. He took the degree of M.B. at Aberdeen in 1869, passing the whole of the professional examinations at one term—a feat which, as Professor Harvey remarked, is "almost never attempted; and the manner in which Dr. Gillies accomplished it evinced mental capacity of a singularly high order." He acted for a time as assistant to Dr. Handyside in the anatomical classes of the Edinburgh School of Medicine, and engaged also in original investigations of a physiological nature, for which he possessed great aptitude, but circumstances did not permit him to follow out his bent. He entered on general medical practice in Melksham, Wiltshire, and for a short time in London. He went to Dunedin in 1874, where he was soon afterwards appointed health officer of the city. As such he took charge of the Fever Hospital, which was erected in consequence of an outbreak of scarlet fever, and by his skilful management he achieved the best results. He was also appointed in 1876 Lecturer on Clinical Medicine at the Otago University. He took a keen interest in all matters affecting the social, educational, and political interests of the community; but from his retiring disposition he preferred to publish his numerous communications on such subjects anonymously. He was a proficient in Celtic literature, to which he devoted much attention. His skill and sympathy and kindness were very highly appreciated by his patients, and very specially by those in humble circumstances, to whom he rendered needed help with ungrudging generosity. He was married in 1879 to Miss Carnegie (granddaughter of the late Captain David Carnegie of Edinburgh), who survives him.

DR. HERMANN REUTER.

ANOTHER medical hero of the Franco-German war died on the 4th inst. at Nürnberg, in the person of the Landgerichtsarzt, Dr. Hermann Reuter. He was born in May, 1826, and having completed the usual course at the Nürnberg Gymnasium, he proceeded to the Erlangen and Heidelberg Universities. At the former of these seats of learning he distinguished himself by his powers of organising the *Burschenschaft* for political as well as academic aims, and lived through the revolutionary upheaval of 1848 in keen sympathy with the movement, but without compromising his professional career. Having graduated creditably as Doctor of Medicine, he served as volunteer assistant surgeon in the Schleswig-Holstein campaign—an

Digitized by Google

experience by which he profited largely and well. His next step was to settle down in his native Nürnberg as a medical practitioner, in which capacity he not only won the confidence of the community, but so attracted the notice of the Government that in 1861 he was appointed Bezirksgerichtsarzt (head medical consultant of the district court). Other professional honours fell to his share—that of Medicinalrath in 1880, and that of the Michaelsorden of the fourth class on New Year's Day of the present year. His chief distinctions, however, and those he mostly prized, were the posts that seemed spontaneously to come to him in the hygienic and charitable undertakings of his native city and province. He contributed towards founding the local medical association, and was an able and active member of the Aerzte-Bund (medical confederation) of Germany. But it was in the war time of 1870-71, particularly in his work on behalf of the wounded of either belligerent army, that he gave most striking evidence of his high qualities of head and heart. His fearless exertions under fire, and his nightly as well as daily service in the field ambulance, earned him the Bavarian Cross of Merit, the Memorial Cross of Saxony, and, above and beyond these decorations, the deep and enduring gratitude not only of his compatriots but of the opposing nationality. In after years he enhanced his reputation in the law courts as an expert in medico-legal cases, while, outside his professional engagements, he was an ardent votary of liberal principles in Church and State—a political leader respected even by the opposite interest not more in Nürnberg than throughout Bavaria. His powers, taxed as they had been by an exceptionally laborious and eventful life, latterly showed symptoms of decline, which, assuming an acute form, carried him off in his sixty-fourth year.

Medical News.

BOY SUICIDES.—On Thursday two boys, aged respectively thirteen and sixteen, are reported to have committed suicide; one by hanging himself, the other by swallowing laudanum.

LEAD POISONING.—A large number of the inmates of the Keighley workhouse and infirmary are stated to be suffering from the effects of lead poisoning. The water, supplied by the Corporation, is suspected to be the cause of the evil.

BIRMINGHAM HOSPITAL SUNDAY.—The collections on behalf of the General Hospital, which will this year receive the proceeds, will be made on Oct. 27th next. Great exertions are being made in the town to recover the ground lost during late years.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A monthly meeting of the North-Western Branch of the Society of Medical Officers of Health was held in Manchester last week, at which M. Bobrownicki, Professor of Mathematics in Russia, read a paper on a new Patented Method for the Treatment of House Refuse. His improvements consisted in the treatment of the putrescible matters by direct contact with the condensible and suspended matters in the gases arising from the ordinary combustion of fuel, or from the distillation at a comparatively low temperature of coal, tar, resin, and other fuels and hydrocarbons. By this means the gaseous products arising and resulting from the imperfect combustion and distillation were deprived of their constituents. which were objectionable in the atmosphere, but were of considerable value to the agriculturist.

BEQUESTS AND DONATIONS TO HOSPITALS.—Mr. Quilter, M.P., has given £2000 to the Felixstowe Convalescent Home.—The late Mr. Wm. Stirling of Glasgow has left by his will £20,000 to Glasgow charities; the three leading infirmaries get £5000 each.—Dr. Edmond of Kingswells has presented £300 to the Aberdeen Hospital for Incurables, as an additional donation in place of future annual subscriptions.—The late Surgeon-General David Wyllie, formerly of Montrose, has left £2500 to the Montrose Infirmary, and a like amount to the public charities.—Mrs. Walter Parlane, late of Somerset-place, Glasgow, has by her will (after providing for legacies to relatives and subject to an annuity still payable) bequeathed to the Glasgow Royal Infirmary and the Glasgow Royal Hospital for Sick Children £1000 each.

RABIES.—According to the *London Gazette*, the number of dogs in England reported during the week ending Sept. 7th as afflicted with rabies was nine, against twelve in the previous week. All were slaughtered. Of the nine diseased animals only one belonged to London proper, whilst two appertained to Kent and Surrey each, and one to Lancaster, Middlesex, Sussex (Eastern Division), and York (West Riding) respectively. In spite of the muzzling order, there appears to be still a steady average of nearly a dozen cases of rabies each week. What the number would have been had the muzzling order not have been enforced may best be left to the imagination. Even as it is, the "order" is scandalously ignored in the suburbs of London; whilst, to make the edict thoroughly effective, it should be made universal; and, furthermore, the authorities should see that the muzzling is carried out.

PROVINCIAL SUNDAY AND SATURDAY HOSPITAL COLLECTIONS.—The Welwyn Hospital Sunday collection on Aug. 11th amounted to £13 13*s.*, which sum has been divided between the Hertford and Hitchin Infirmaries and the Hertford Convalescent Home. The St. Albans (Herts) Hospital Sunday collection on Aug. 18th produced £24 2*s.* The Bank Holiday Hospital Gala held at Leeds on the 5th ult., in aid of the Leeds medical charities, realised about £600. The Hospital Saturday collection at Clacton-on-Sea, on behalf of the Essex and Colchester Hospital, held on the 17th ult., amounted to £50 4*s.* 7*d.* The usual annual Church parade of the Friendly Societies, in aid of the Bath Royal United Hospital, on Sunday, August 25th, produced £26. The Hospital Saturday collection at Scarborough, on the 7th inst., towards the funds of the Scarborough Hospital and Dispensary, amounted to £182 12*s.* A church parade of the United Friendly Societies of Teignmouth on Sunday, the 1st inst., on behalf of the Teignmouth Infirmary, produced £21 10*s.* The Maidenhead Friendly Societies' Hospital Sunday collection on the 8th inst., on behalf of the Maidenhead Cottage Hospital, amounted to £35 7*s.* 5*d.* The Hospital Sunday collection on the 15th inst. at Dartmouth amounted to £24 18*s.* 11*d.*; and that of Northallerton on the same day realised £6 3*s.* 6*d.*

GLINN, C. F., L.R.C.P.Lond., M.R.C.S., L.S.A., has been appointed Medical Officer of Hatherleigh District, Okehampton Union.

GREENE, A. J., L.R.C.S., L.K.Q.C.P.Irel., has been appointed Medical Officer of the Burwash District, Ticehurst Union.

MCWHANNELL, L., M.B., C.M.Glas., has been appointed Senior House Surgeon to the Birkenhead Borough Hospital, vice E. Scott Sugden, M.B., M.R.C.S., resigned.

MEDCALF, E. S., L.R.C.P., L.M. Edin., M.R.C.S., L.S.A., has been appointed Medical Officer for the Town of Hove, Sussex.

MUGFORD, S. A., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Ardleigh and Great Bromley Districts, Tendring Union.

PACKMAN, ALFRED C. A., M.D., M.R.C.S., has been appointed Medical Officer of Health for the Rural Sanitary District of the Hoo Union.

PURSLOW, C. E., M.D.Lond., M.R.C.S., Honorary Medical Officer to the Birmingham Lying-in Charity, has been appointed Honorary Obstetric Officer to the Queen's Hospital, Birmingham, vice A. T. Hawkins, F.R.C.S., resigned.

REED, LESTER, F.I.C., F.C.S., has been appointed Public Analyst for the Borough of Croydon.

SNELLEN, HERMAN, jun., M.B. and Mast. Surg. Utrecht Univ., has been appointed House Surgeon to the Bristol Eye Hospital.

THRESH, J. C., D.Sc.Lond., M.B., B.Ch.Vic., has been appointed Medical Officer of Health to the combined Sanitary Districts of Chelmsford and Maldon.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BOSCOMBE HOSPITAL AND PROVIDENT DISPENSARY, Bournemouth.—Resident Medical Officer. Salary £60 per annum, with board and residence at the hospital. Not more than five testimonials of recent date to be sent.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—House Physiciancy. No salary, but board and lodging are provided free of cost.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—House Surgeon. Salary £70, with board, washing, and residence.

FLINTSHIRE DISPENSARY, Secretary, Bagillt-street, Holywell.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free; also coal, lights, water, and cleaning, or in lieu thereof the sum of £20 per annum.

GENERAL HOSPITAL, Birmingham.—Resident Registrar and Pathologist. Salary £100 per annum, with board and lodging. Also Assistant House Surgeon, for six months. No salary, but residence, board, and washing will be provided.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Resident Medical Officer. Salary £50 a year, with board and lodging.

HULL FRIENDLY SOCIETY MEDICAL INSTITUTE, Brook-street, Hull.—A fully qualified Man to take charge of, and manage the above. Salary 170 guineas per annum, with midwifery fees, house, coals, and gas.

LEICESTER INFIRMARY AND FEVER HOUSE, Leicester.—House Surgeon. Salary £120 for the first year, rising at the rate of £10 per annum until the fourth year. Board, apartments and washing will be provided.

LONDON FEVER HOSPITAL, Liverpool-road, Islington, N.—Assistant Resident Medical Officer. Salary £120 per annum.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Junior House Surgeon. Salary £40 per annum, with board and residence.

NORTHUMBERLAND COUNTY ASYLUM, Morpeth.—Clinical Assistant. No salary, board and residence provided.

ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY, Wigan.—Junior House Surgeon. Salary £80 per annum, with apartments and rations (exclusive of wines, spirits, and washing).

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Junior House Surgeon. Salary £50 per annum, with board and apartments.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King-William-street, West Strand.—Surgeon.

SOUTH DEVON AND CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary £100, with board and rations.

Births, Marriages, and Deaths.

BIRTHS.

CONNOLLY.—On Sept. 17th, at the Royal Arsenal, Woolwich, the wife of Surg.-Major B. Bloomfield Connolly, M.A., F.R.C.S., of a daughter.

DINGLE.—On Sept. 17th, at 46, Finsbury-square, E.C., the wife of Wm. A. Dingle, of a daughter.

GARDNER.—On Sept. 13th, at The Avenue, Mill-hill-park, Acton, the wife of Dr. W. T. Gardner, of a daughter (Marjorie).

JONES.—On Sept. 5th, at Longworth-road, Oxford, the wife of Arthur Wentworth Jones, B.A., M.R.C.S., L.R.C.P., of a son.

KYLE.—On Sept. 15th, at St. Andrews, N.B., the wife of Dr. Hamilton Kyle, of a daughter, stillborn.

MARSH.—On Sept. 14th, at Russell-road, Kensington, the wife of W. Blake Marsh, L.R.C.P., M.R.C.S., late of the P. and O. Co.'s Service, of a son.

NICHOLS.—On Sept. 7th, at Alderney, the wife of Surgeon F. P. Nichols, M.B. Cantab., Army Medical Staff, of a daughter.

MARRIAGES.

BARRINGTON—TAYLOR.—On Sept. 12th, at St. Nicholas' Church, King's Lynn, Frederick Albert Barrington, L.K. and Q.C.P., and L.R.C.S.I., of Chapel-street, King's Lynn, to Frances Emma, only daughter of the late Charles Taylor, Esq., of King's Lynn, Norfolk.

CROSS—HAWKES.—On Sept. 11th, at St. Matthias' Church, Torquay, Francis Richardson Cross, M.B. Lond., F.R.C.S., of Clifton, eldest son of the late Rev. Joseph Cross, M.A., Vicar of Merriott, Somersetshire, to Eva Beatrice, elder daughter of the late Capt. Henry Hawkes, R.N., of Torquay.

DAY—MITCHELL.—On Sept. 10th, at Zion Church, Rathgar, William Bullen Day, Army Medical Staff, son of Arthur M. Day, Rostrevor-terrace, to Ruth, younger daughter of the late George Mitchell, J.P., Hopeton, Rathgar, Dublin.

GATHERGOOD—BEATLEY.—On Sept. 11th, at St. Mark's Church, West Hackney, Benjamin William Gathergood, M.R.C.S., L.S.A., son of John Gathergood, Surgeon, of Terrington St. John, to Kate Mary (Kitty) Beatley, second daughter of Thomas Gage Beatley, Shipowner, of Leadenhall-street, London, and Amhurst-road, Hackney Downs.

GRIFFITH—LOVELL.—On Sept. 18th, at St. Mathias', Earl's-court, Dr. R. Glyn Griffith, of Allahabad, N.W.P., India, to Edith Lilian Grimsted, only daughter of the late John Lovell, Esq., of Portledge House, Newbridge-hill, Bath, Inspector-General of Hospitals, Madras Presidency.

HAY—MACGREGOR.—On Sept. 14th, at Holy Trinity Church, Llandudno, by the Right Rev. the Bishop of Bangor, and the Rev. J. Morgan, Rector of the Parish, Henry Hay, M.B., C.M. Edin., and Surgeon to the Prison of Edinburgh, to Jessie Mackay Macgregor, widow, daughter of the late Rev. David Nicol, of Dalgety, Fifeshire, N.B., and niece of James Nicol, M.D., Llandudno.

HAYNES—NEWMAN.—On Sept. 11th, at the Parish Church, Bottisham, Cambs., Walter F. Haynes, L.R.C.P., of Stansted, Essex, to Rosa, second daughter of Edward Newman, Esq., of the Parsonage, Bottisham.

MACKAY—BOURNE.—On Sept. 12th, at Tynemouth Parish Church, by the Rev. Canon Brutton, Vicar and Rural Dean, assisted by the Rev. R. Raggett, M.A., William Murray Mackay, L.R.C.P., L.R.C.S., L.F.P.S.G., &c., of North Shields, second son of James Mackay, Esq., Geiselittle House, Caithness, N.B., to Edith Rose, third daughter of the late William Bourne, M.A., M.D., J.P., of North Shields.

MCKERCHAR—BRYER.—On Sept. 17th, at Christ Church, Forest-hill, Robert McKerchar, M.D., of Dalbeattie, Kircudbrightshire, to Edith, eldest daughter of William Bryer, of Sunderland-road, Forest-hill, and Barbican, London.

NICHOLSON—COX.—On Sept. 10th, at Hackney Parish Church, Thomas Tanner, only son of the late William Hunter Nicholson, M.R.C.S., of St Pancras, to Susan (Susie), eldest daughter of Isaac Cox, Esq., of Dalston.

TOPHAM—WORSICK.—On Sept. 11th, at North Parade Baptist Chapel, Halifax, by the Rev. Carey Hood, resident minister, assisted by the Rev. W. Gray, of Birchcliffe, Albert Stocks Topham, M.R.C.S., L.R.C.P. Lond., Prescott-street, Halifax, to Anna, eldest daughter of Richard Worsick, maltster, Halifax.

DEATHS.

BENTON.—On Sept. 8th, at Weymouth, after a few days' illness, Samuel Benton, M.R.C.S., of 2, Bennett-street, St. James's, second son of Philip Benton, of North Shoebury, Essex, aged 39.

DUCKWORTH.—On Sept. 14th, at Westgate-on-Sea, after a short illness, Annie Alicia, wife of Sir Dyce Duckworth, M.D.

EDSALL.—On Sept. 14th, at Clarence-road, Kew-gardens, Surrey, Samuel Bernard Alfred Edsall, M.R.C.S. Eng., second son of W. Viner Edsall, of Wimbledon, aged 31.

GARDEN.—On Sept. 14th, suddenly, at South Hampstead, Alexander Garden, M.D., late Brigade Surgeon I.M.D., aged 56.

HENDERSON.—On Sept. 7th, at Brighton, George Henderson, M.R.C.S., late of Upper Norwood, in his 30th year.

MURRAY.—On Sept. 16th, at Rickmansworth, Herts, John Leslie, younger son of Alexander Dalton Murray, M.B.

ROYSTON-PIGOTT.—On Sept. 14th, at Annandale, Grange Gardens, Eastbourne, George West Royston-Pigott, M.D., F.R.S., aged 70.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

ANTISEPTICS AMONGST THE ANCIENTS.

DR. ANAGNOSTAKIS, Professor of Ophthalmology in the University of Athens, writing in the Greek medical journal, Γαλληνὸς, points out that the ancient Greek physicians were acquainted not merely with the words σῆψις (putrefaction) and ἄσηπτος (non-putrescible), but with the great fact of what we now term septic action, and with the importance of preventing it in surgical cases. Thus Hippocrates recommends that wounds should be dressed with hot water, and in the treatment he employed as far as possible rain-water, boiled, in order to render it aseptic: ἀποσήπεσθαι. He also recognised that suppuration was due to putrefaction, and that putrefaction was due to moisture; consequently he laid considerable stress on the drying of wounds. If the book "On Wounds" is carefully read, it will be found to form a small code of antiseptic or aseptic treatment. As to the substances used as dressings, we know the Good Samaritan employed oil and wine, and Hippocrates recommended tar in the form of ointment and sulphate of copper in the form of powder Besides these substances, bitters, aromatics, and resins were looked upon as valuable antiseptics.

Mr. T. G. Simpson.—1. We do not think the prospects of practice of a man unconnected with the Indian Medical Service would be good. 2. There is no special work on the subject. There is much information in Dr. Blanford's reports on the Meteorology of India; and Dr. Macnamara has published a work on Himalayan India, its Climate and Diseases (Churchill).

Mr. H. Booth.—We are not aware of any injurious results having arisen from the smoking of "asbestos" pipes.

THE RESPECTIVE CLAIMS OF PRINCIPALS AND ASSISTANTS AS TO FEES.

To the Editors of THE LANCET.

SIRS,—A. is called out to a case of drunkenness, and the case goes to court. A. is assistant to a doctor, and the latter has never bothered himself about the case. All the responsibility of the case lies upon the assistant A. The case comes on, and A. gets £1 1*s.* for his labour. The doctor, however, claims half fee. Note, however, that this case did not interfere in any way with the due performance of A.'s duties. Should A. not receive the whole payment, or is the doctor capable of claiming half fee?

Would you kindly find room for the insertion of the above in your journal, as also its solution? I am, Sirs, yours truly,

September, 1889. J. W. M.

*** A. must be considered as acting throughout as an assistant, not as principal. Apart from any contract to the contrary, as regards odd fees, it seems to us that the division of the fee was right.—ED. L.

OUR STUDENTS' NUMBER.

London School of Medicine for Women.—By a printer's error, the name of Mr. Dawson was substituted for that of Mrs. Dowson as lecturer on forensic medicine and hygiene.

J. O'C.—"The Italian Medical Association," like its German analogue, publishes an official report of its transactions, the papers and speeches being revised by their authors. The title of the volume in which the work of the Association's first meeting is recorded is: "Lavori dei Congressi di Medicina Interna." It numbers 400 pages; its editor is Dr. Edoardo Maragliano, and its publisher is Vallardi, of Milan.

Mr. J. Thomas.—What "new Act" is referred to?

REMARKABLE CASE OF MATERNAL IMPRESSION.

To the Editors of THE LANCET.

SIRS,—In one of your issues of some months ago—in May last I think—Dr. Russell of Paisley recorded a case of what he took to be one of "maternal impression." The cardinal facts of it were these. The wife of a glazier was *enceinte* at the time her husband unfortunately met with an accident—a severe wound of his right forearm—so serious that it was deemed necessary to take him to a hospital, where for a few days it was feared he would lose his hand. When her baby was born a nævus was found on the corresponding part of its forearm. This case is similar to that of the Countess of Cromerty, related by Sir Walter Scott in his "Tales of a Grandfather." She was in one of her pregnancies when her husband, the Earl, was tried and condemned to death for the part he took in the rebellion of 1745, caused by the Pretender Charles Stuart. Through the powerful intercession of his Countess and that of her friends he was pardoned by King George, but when afterwards his wife presented him with a son there was a mark of a broad axe on the child's neck, on that part of it where at one time she feared the headsman would have to operate. No doubt in both cases the anxious mothers thought intensely of their unfortunate husbands—the one in danger of losing his hand, the other his head. My case is more remarkable and interesting to medical men than either of these, and among several cases occurring in my practice recently it is the strangest and most extraordinary.

I was asked to see a woman in a neighbouring village who was being attended by a midwife; the latter, however, being unable to effect delivery by herself, wanted a doctor. On introducing my finger to ascertain the presentation I perceived something unusual—a long, round, and slightly tapering fleshy substance, which struck me at the time as feeling like the shape of an ordinary carrot, but of course not so hard. But to what part of the body this substance was attached was a puzzle, until I discovered what I took to be an ear and the eyes. I then concluded it must be attached to the head. Giving a dose of ergot, and stimulating the uterus by other methods as much as possible, I soon had come into the world what I at once saw was a monster. Instantly wrapping it into the piece of flannel ready to receive it, and without saying a word either to mother or nurse, I carried it into an adjoining bedroom, followed by the latter. Here I found the fleshy substance spoken of to be projecting from the floor of the skull, the roof of which was entirely absent, and so closely did this substance resemble a cow's teat—or, as the nurse called it, "pap"—that at the same instant we both made the same exclamation, "How like a cow's teat!" Cautioning the midwife to observe the strictest silence while I questioned the mother, we again proceeded to her room, when I quietly said to her, "I am sorry to have to tell you, Mrs. C——, that the child is dead, although it breathed a few moments; and perhaps it is as well, because the baby was not 'all right.'" "Ah!" said she, "I thought that such would be the case. What is wrong with it?" I replied, "Tell me your story first. What caused you to think it would not be 'all right'?" "Well," she proceeded, "I got a most awful scare when I was carrying it at the fore part of my time." Here she paused, but, leading her on by an inquiring "Yes?" she went on again—"One day I was in the cowhouse, milking the cow, sitting upon the stool beside her and milking away, when a rat or something in the roof made such a row all at once as to startle the poor animal almost out of her wits, and before I knew where I was she had tumbled me on the floor, milk and all together, and there I was, lying upon my back, still hanging on to the cow's pap like grim death, and thinking that I would be trampled to death every moment. Oh, the scare! I shall never, never forget it! for it made me downright ill and nervous for weeks after it. I could not get it out of my head, and kept dreaming about it even, and I feared all along for my child." Having thus spoken, she made signs for me to bend down my ear towards her, when she whispered: "Has it horns upon it, doctor?" Nothing would induce the mother or friends to give up the body of the child, nor would she allow me to touch it further, which caused me the sharpest disappointment. The "teat" seemed to be a prolongation of the spinal cord, and to be all there was to represent the brain. Otherwise the body was well developed and perfect.—Yours truly,

Revesby, Lincolnshire, Sept. 3rd, 1889. A. ROSS PATERSON, M.D.

FALLING HAIR.

To the Editors of THE LANCET.

SIRS,—With regard to the letter of "Scarpa" in your last issue, I beg respectfully to suggest the following remedy, which I, in my limited experience, have found most useful in such cases. ℞ Tinct. jaborandi, ʒss.; lanoline, ʒiii.; and glycerine, ʒii. A little to be rubbed in every night.

I am, Sirs, yours obediently,

Sept. 17th, 1889. F.

VACCINATION AWARDS.

Public Vaccinator.—The awards have in one sense certainly not been discontinued; but under the Local Government Act of last year they are now payable by the County Councils on receipt of the proper authorisation from the Local Government Board. Why delay occurs in the issue of the needed authority is by no means clear; and inquiry should be made at Whitehall with a view of ascertaining why awards which are long since overdue have not been paid.

Vera.—We regret that we cannot insert our correspondent's letter. His personal remarks on the examiners are, we believe, unjust. Our advice to him is to read up for the next examination.

M.D.—We would advise our correspondent to put himself in communication with the Secretary of the Income-tax Repayment Agency, 16, Artesian-road, W.

Dr. G. S. Middleton.—We shall be glad to receive the MS. for consideration.

FACE PRESENTATIONS.

To the Editors of THE LANCET.

SIRS,—Two consecutive cases of face presentation falling to my lot to attend on the same day seemed to me to be rather an unusual occurrence. I thought I might make a few remarks on them. The first, Mrs. H——, was in her third labour. On examining her I found the os nearly fully dilated, the membranes being still intact. These ruptured shortly after, and I then discovered the true nature of the case. The descent was fairly rapid until the chin appeared at the vulva, when from some cause there was considerable delay. Having fears for the safety of the child, I applied the forceps, and delivered without difficulty.

I was called to the second case, Mrs. M——, the same evening—her thirteenth pregnancy, all her previous ones being natural. The membranes had ruptured two days before. On examining her I found the face presenting high up at the brim, but fairly movable. Judging that there was plenty of room, I decided to leave the case to nature. For about an hour and a half there was little or no advance, although the pains were very good, when suddenly the head descended on the perineum, and the child was born without difficulty.

I have noticed that several authorities advocate in these cases either early version, or an attempt to rectify the malpresentation. In the first of my cases either of these methods was impracticable, as the head was quite fixed when assistance became needful; and in the second, which looked at first a proper case for turning, owing to the early delay, the procedure proved quite unnecessary after a little patient waiting. From my experience, I am inclined to leave such cases to nature; but I would be glad to hear the views of others of your correspondents on the subject.

I am, Sirs, yours truly,

Lancaster, Sept. 16th, 1889. GEO. R. PENROSE, L.K.Q.C.P.I., &c.

L.R.C.P.Lond.—Any legally qualified medical practitioner is entitled to take or use the title of Dentist, Dental Surgeon, &c.; but he cannot now register under the Dentists Act without taking the special diploma.

DISPENSING LABELS.

To the Editors of THE LANCET.

SIRS,—In reply to "A. R. J.," I think he will find the method I usually adopt an excellent one for preserving his labels, besides adding much to the appearance of the bottles and surgery. I have used it for the last three or four years, and with always satisfactory results. When the labels have been placed on the bottles and are quite dry, apply to them with an ordinary camel-hair pencil a coating of size, made liquid by means of a hot-water bath. When this has quite dried on, paint the labels over with ordinary varnish, or, if a darker colour is required, with varnish-stain. When this has properly dried, the labels will be ready, and with careful use will often last for two or three years, being easily washed with a damp sponge. Care should be taken to cover the whole of the label with size, else a dark patch will appear when the varnish or stain is applied. Trusting "A. R. J." will find this method answer as well as I have done,

I remain, yours faithfully,

Kingston-on-Thames, Sept. 16th, 1889. DISPENSER.

To the Editors of THE LANCET.

SIRS,—I would suggest to your correspondent, "A. R. J.," that if he varnishes the labels on his dispensing bottles with some white hard photographic negative varnish, he ought to find no difficulty in gently washing them and keeping them clean.—Yours obediently,

Belgrave-road, S.W., Sept. 15th, 1889. THOS. CHARTERS WHITE.

ABSTRACT OF A

Clinical Lecture

ON

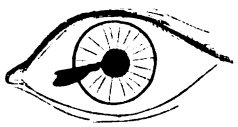
FOREIGN BODIES IN THE EYE.

By C. S. JEAFFRESON, M.D., F.R.C.S.,

SENIOR SURGEON TO THE NORTHUMBERLAND, DURHAM, AND NEWCASTLE INFIRMARY FOR DISEASES OF THE EYE.

AFTER dilating upon the more common form of injuries, Mr. Jeaffreson said:—I wish to explain to you the rule of practice I adopt where there is supposed to be a forming body in the eye. Of course where there is an extensive rupture and sight is obviously and permanently destroyed, search may be made in the eye if desirable, but it can scarcely ever be necessary, as evisceration or enucleation should always be immediately performed. It is in cases where the wound is not so extensive, where there is still perception of light, that we shall have some hesitation as to how to act. Let me give you a case in point. A man was brought to the hospital with the history of having been struck with a piece of metal chipped from a tool. There was a wound three-eighths of an inch long dividing the cornea at its junction with the sclerotic, the iris was also split, a small piece was prolapsed. (Fig. 1.) There was a good deal of blood in the anterior chamber, but still fair perception of light. The patient could count fingers at one or two feet with his back to the light. How should we proceed in such a case? If there is a foreign body in the eye and it remains the eye is doomed to destruction. If there be none, there is a prospect of retaining the eye, which, although seriously damaged, is better than an artificial organ. In this case it is obviously of the very first importance to determine if there is a foreign body in the eye, and to leave no stone unturned which will help us in determining that point. First, we must have a minute and careful history of the case, and collect all the outside testimony which can be brought to bear upon the point. The object from which the foreign body has become detached should, if possible, be produced. In the present case the tool is a cold chisel, and the piece detached about three-eighths of an inch by two-eighths. (Fig. 2.) It has not been found or picked up in the shop. This is a point in favour of its being lodged in the eye, though not of very great importance, as such a small object might elude search. Can we derive any information from the nature of the wound? The cornea is cut, the aqueous has escaped, the iris is incised, and the cavity of the vitreous is opened. Under these circumstances, it is exceedingly improbable the piece should have made such a wound and fallen out again, unless it were a large piece, which we know it is not. To obtain corroborative evidence we employ the magnetic needle. The needles that I employ were manufactured for me by Messrs. Milward and Co. of Redditch. They consist of a very fine double-pointed needle about one inch in length, with a fine eye in the centre. A very delicate piece of silk is passed through the eye and knotted, and the other end is attached to a small ivory handle as seen in the sketch. The length of the silk must be such as to give the needle sufficient play to sew with, and something about twelve inches is sufficient for this. (Fig. 3.)

FIG. 1.



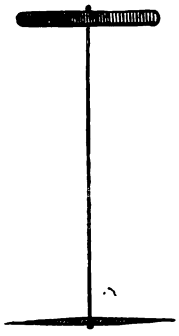


FIG. 2.

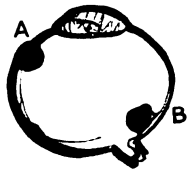

FIG. 3.

The patient must be now placed upon a couch so that the commissure of the eye lies north and south, and the needle gradually lowered over the organ. Opening the commissure widely, the needle is promenaded over the globe as close as possible without touching it, and the patient is also directed to facilitate matters by moving the eye to the greatest extreme in different directions. If this be carefully and steadily done, and the needle remains perfectly steady, the inference is that there is no piece of metal (steel or iron only) in the eye. This is, however, only negative evidence; its sources of fallacy I shall allude to presently. In the event of there being distinct deflection, we have positive evidence of a piece of metal, and that probably of a considerable size. The magnetic needle may therefore be of the greatest value to us in these cases, and its employment should never be neglected. As I said before, sometimes it is uncertain in its action. This may arise from two causes—either the piece of metal is too small to influence the needle, or it may lie at too great a depth.

From experiments made upon eyes which have been enucleated and animals' eyes, I find that a piece of metal weighing two or three grains, lying immediately under the sclerotic, will very sensibly and obviously deflect the needle; a piece the same size lying at the opposite extremity of the eye will not do so, the substance of the vitreous proving an obstruction to the magnetic current. (Fig. 4.) If the piece were double the size it would do so in any position. So you see the chances of getting the reaction upon the magnetic needle depends much upon the size of the fragment and its relation to the surface. In experiments made upon eyes removed we can approximate the needle to all parts of the surface of the globe; but when the eye is *in situ*, a comparatively small part of it can be so explored, and this introduces an element of failure. In making the test we must be careful to see that the needle does not come into contact with the lashes, and thus obtain an artificial deflection. In some cases, to facilitate matters, it may be necessary to cut the lashes short. You must not either be led astray by the adhesion of the point of the needle to the globe. If the point touches the globe by accident it will most certainly adhere, and requiring a little force to draw it away will give the impression of magnetic attraction. What we wish to see is lateral deflection or an oscillatory movement of the needle, which a few trials will make you familiar with. Well, in our illustrative case, the deflection of the needle was very obvious, and I was able to diagnose with certainty the presence of the piece of metal. The galvanic probe was cautiously introduced into the vitreous; a slight click was felt, and the probe cautiously and slowly withdrawn. When the piece of metal arrived at the internal opening of the wound it could not be drawn through, owing to its not coinciding with the position in which it originally entered the eye. This is a common occurrence, and one we should always be prepared to deal with. It is better immediately to enlarge the wound in the direction where the enlargement will cause least danger to ocular structures (generally backwards) than to let the body slip and attempt to get it attached to the probe in a more favourable position. I therefore enlarged the wound with a cataract knife, and the piece was readily extracted. The piece of prolapsing iris was now abscised and a conjunctival suture inserted close to the margin of the cornea. In this case everything pointed to the presence of the foreign body in the globe, and we had the positive evidence of the magnetic needle. Had it not been so, I think we should still have been justified in making a careful search for the foreign body. If it is carefully and gently done with a perfectly clean instrument, it can scarcely increase the mischief of the original injury. Of course what I say applies only to particles of iron and steel. With other materials which cannot be secured by means of the galvanic probe we shall scarcely be justified in searching, because if we found a foreign body we could rarely extract it without making a large opening for the introduction of the forceps. An exception to this rule must be made in the event of the foreign body being absolutely seen *in situ*. This sometimes happens when the patient is brought immediately after the accident, and the media and structures of the eye are still transparent. Under these circumstances I have occasionally been able to remove pieces of stone, copper, brass, &c.,

FIG. 4.

Digitized by Google

using, when the body was small, a pair of cannula forceps; when it was large, a pair of aural forceps. It is rare, however, that the circumstances are sufficiently favourable for us to carry out these manœuvres; as a rule we must be content to wait till symptoms develop themselves. In the event of the foreign body being large and of an irritating nature, a panophthalmitis will rapidly develop; under the contrary circumstances the body may become encapsulated or encysted and the eye quiet down, retaining sight in various degrees, from perfect vision to the mere perception of light.

I now wish to say a few words about another class of cases which are comparatively common, and always fraught with great anxiety and responsibility for the surgeon. I allude to those cases in which a small foreign body penetrates the cornea, and becomes lodged in the iris. The shock of the accident may have been so slight as perhaps scarcely to attract the patient's notice; yet the results may be of the most serious import. I cannot do better than illustrate what I have to say by a case which has occurred to me lately.

A smith at work in his forge felt something strike his eye. It gave him comparatively little pain, and he never for a moment suspected anything serious had happened to him. In the course of the day he applied to a local doctor, who told him there was nothing in the eye, but gave him a little soothing lotion. A few days after he applied to me. The eye was injected, painful, and tender. There was some serous iritis, and on the edge of the pupil near to the margin could be seen a small nodule of lymph. This, I suspected, contained a foreign body, more especially as the traces of a minute wound could be seen in the cornea. I explained my view to the patient, and pressed upon him the necessity of allowing me to attempt its removal. This he consented to do. Being a powerful and apparently a strong-willed man, I consented to make the attempt without chloroform. An incision about four millimetres in length was made in the margin of the cornea opposite this nodule of lymph and a curette introduced. On touching the nodule the lymph crumbled away, and the glistening surface of a metallic particle was seen—a flat scale not larger than a small pin's head. I tried to coax it into the curette, but it remained immovable, so I resolved to remove it by forceps together with the piece of iris to which it was attached. No sooner had I seized it together with the piece of iris than the patient gave a sudden and uncontrollable jump, at the same time violently rotating his globe. A large piece of iris was dragged from its attachment, the anterior chamber became filled with blood, but whether the piece of metal escaped or not it was not possible to decide.

The result of this case will no doubt be unfortunate, but I can scarcely attach any blame to myself owing to want of skill, though I do for not having refused to operate without chloroform being administered. In the whole range of ophthalmic surgery there are no cases which require greater care, greater dexterity, greater patience, and greater steadiness on the part of the patient than the extraction of foreign bodies in the anterior chamber; for these reasons, therefore, unless under the most urgent circumstances, no attempt should be made to remove them unless the patient is thoroughly anæsthetised. Some years ago my own son was struck by some particles of glass from an exploded bottle; one fragment penetrated the cornea, and could be seen in the anterior chamber; another was lodged in the cornea. Not anxious to undertake the responsibility myself, I telegraphed to my friend, Sir Wm. Bowman; but, learning that he was on the Continent, and fearing delay, I resolved finally to operate. The piece lodged in the cornea was easily removed. The fragment in the anterior chamber was about the size of a hempseed, but irregular and many-angled; it was freely movable, and changed places with the position of the head. Sometimes its position was difficult to distinguish, but usually it lay in the angle at the bottom of the cornea. An incision about five millimetres in length was made in this situation in the sclero-corneal junction, with an angular broad needle, and the fragment extracted with a little manipulation. In this case chloroform was administered by my friend Dr. Nesham, and the result of the operation was most perfect. In some text-books I see that it is recommended not to interfere with foreign bodies in the eye which are unattended by active symptoms. I think cases where such advice can be safely followed must be rare indeed. Where there is a movable body in the anterior chamber it should unquestionably be removed under any circumstances, and in my experience wherever the foreign body is situated the chance of a successful operation is always much greater when there are no symptoms than when these have actually developed. The only exception that perhaps should be made to the immediate extraction of a foreign body is when it is quite small, and is lodged in the vitreous chamber. In this situation it frequently interferes but little with vision, is much more likely to become encapsulated, and unless it is a piece of iron or steel, which can be dealt with by means of the galvanic probe, will require such a large incision for its extraction and so much manipulation that there is great risk of immediate loss of vitreous or secondary suppurative hyalitis.

No one who has not had frequently to perform these operations can imagine the difficulties that may arise. The foreign body is there, clearly visible, and it would seem a simple matter, but it is as trying to the eye, the hand, and the patience as the "pigs in clover" puzzle. As soon as the incision is made the cornea collapses and the object loses its distinctness; now a few drops of blood may exude and cloud all; the foreign body, if attached to the iris, may be difficult to detach; it may fall out of sight between the cornea and the angle of the iris; it may slip through the pupil, or if the iris has been transfixed may tumble through without any warning. I know of no more pleasant feeling of thankfulness than that which one experiences when such an operation comes to a satisfactory and successful termination. It might seem superfluous to warn you against mistaking pigment deposits in the iris for foreign bodies; yet I can assure you the warning is not by any means unnecessary. I have on more than one occasion seen this mistake made by very competent men. A clear and uniformly coloured iris with a single spot of dark-coloured pigment may (when there are a history and symptoms indicative of a foreign body in the eye) lead you astray unless you make a careful examination with oblique illumination, using at the same time a powerful magnifying glass.

Before I finish I wish to call your attention to a case which has recently passed through our hands, in which a considerable piece of metal was lodged in the lens. The subject of it was a young man who was a fitter. Whilst dressing some castings, a piece flew and struck his eye. We did not see him till a week after the accident, and at that time the eye was only slightly injected, the pupil dilated. (He had been under treatment elsewhere.) The cornea showed, a little to the nasal side of its centre, traces of a recently healed wound. The lens was cataractous, but in the centre there was a dark shadow, which suggested the possible presence of a foreign body. There being but comparatively little reaction, no excessive swelling of the lens, and no absolute certainty of the presence of a foreign body, it was resolved to watch for a few days, keeping the pupil fully dilated with atropine. About the fourth day the swelling of the lens had considerably increased, and the intraocular tension having risen, it was resolved to extract the lens. The incision having been made, there was a gush of lens matter, a considerable piece of metal (about eight grains in weight) presenting at the wound and being removed by a pair of forceps. The patient recovered with a perfectly sound movable pupil and good vision. The lens is of course frequently of necessity wounded when a foreign body penetrates the eye, but it is comparatively uncommon that a foreign body becomes lodged in it without further complications. If it is very small—such as a fine scale of metal or grain of powder—it may do but little injury, producing only a limited opacity in its own immediate vicinity, which may remain quiescent and never spread. If, however, it is large and a considerable rent has been made in the capsule, allowing free access to the aqueous humour, a general opacity of the lens will soon occur. In this case we should watch the case carefully, allowing time for the whole lens to become opaque and softened, but not allowing sufficient time for it to become perfectly diffluent, lest the weight of the particle causes it to become dislodged, and it falls into the deeper parts of the eye, when it would certainly set up acute and dangerous symptoms.

To recapitulate, then, briefly the chief points of my remarks, I should say: 1. When an eye is hopelessly and irremediably destroyed it should be at once removed. 2. When an eye does not appear to be irremediably and hopelessly destroyed every effort should be made to retain it. If there is reason to suppose it contains a foreign body a search may be made, provided always that there is reason-

Digitized by Google

able probability that the foreign body will be removed and the damage to the eye not increased in an important degree. 3. In removing foreign bodies that are attached or embedded in the iris chloroform should be freely administered. 4. Foreign bodies embedded in the lens, and not involving other structures, should not be removed too early; time should be given for the whole lens to soften and liquefy. I regret that time and space forbid me, on this occasion, from speaking concerning that interesting class of case where a foreign body of small size penetrates the globe and becomes lodged upon the retina, being visible with the ophthalmoscope, and producing no other symptoms than a small fixed scotoma. During the last twenty years several cases of this kind have occurred in my practice, and I hope to make them one day the subject of a special lecture.

ON THE DIAGNOSIS AND TREATMENT OF SCROFULOUS GLANDS.

BY W. KNIGHT TREVES, F.R.C.S.,
SURGEON TO THE ROYAL NATIONAL HOSPITAL FOR SCROFULA.

I PREFER the term scrofulous glands to that of scrofulous adenitis, because it is, in the first place, a term sanctioned by long use; and, secondly, because it is less open to objection on the score of incorrectness. Scrofulous glands are not always inflamed, nor is the scrofulous or tuberculous deposit, although the result of, always attended with, inflammation.

The diagnosis of scrofulous glands is for the most part easy, and it is only in exceptional cases that any difficulty arises. The diagnosis has to be made between simple adenitis on the one hand and glandular growth, or hypertrophy of the nature of lymphadenoma, on the other. As regards simple adenitis, time soon settles the question. Simple adenitis is of short, scrofulous disease of long, duration. In simple adenitis the inflammatory exudation in the gland is resolved, or it suppurates within a reasonable time. If, on the contrary, the gland remains enlarged, say, for three months, either it is scrofulous or is in a likely condition to become so. A second point is that the gland affected by simple inflammation is, as a rule, and especially so if about to suppurate, less defined and more surrounded by hard inflammatory material than the scrofulous gland is likely to be. The gland, with its surroundings, is in simple inflammation generally more painful and tender, and especially has more surface tenderness than the scrofulous gland; the skin too is more often red and hot; in fact, the inflammation is more general and more acute. If the degree of simple adenitis is so slight as to cause merely some enlargement of the gland without induration, pain, and surrounding inflammatory exudation, the case is trifling, and the swelling will probably subside as soon as the source of irritation is removed. No doubt there is a borderland between simple adenitis and scrofulous gland disease. We may imagine, although it is perhaps difficult to demonstrate, a prescrofulous state or condition in a gland. By this I mean a gland which, inflamed and enlarged from local irritation, in a person who has some scrofulous tendencies, hangs fire when the local cause has been removed, and, without exhibiting the distinct characteristics of a scrofulous gland, hesitates and declines either to subside or to suppurate. Here I would refer, as helping the diagnosis, to what I may term the "scrofulous throat." In the throat is to be found the earliest indications of scrofula. The scrofulous throat consists of more or less enlargement of the tonsils, probably with signs of old or recent inflammation and ulceration, together with some amount of post-nasal or pharyngeal catarrh, perhaps adenoid growths and an arched palate. Probably not more than one in ten or twenty children with these throats ever suffer from scrofulous glands in the neck or elsewhere, but, on the other hand, it is exceedingly rare to find scrofulous cervical glands in a child with a perfectly healthy throat. A healthy throat should be taken to mean clean, well-defined arches of palate, pale, unthickened mucous membrane, no enlargement of tonsils, and no chronic catarrh. Thus, then, if a gland in the neck has been enlarged for two or three months, if the child has a scrofulous throat, and if there be any family history of consumption or scrofula, the case may safely be put down as scrofulous. This will be more certain still if the child is in poor health, if the circulation is feeble, and if it has that doughy thickening of the cellular tissue which is so common in scrofula. There is also generally to guide us the solid inelastic feeling of a scrofulous gland, which is, as a rule, quite different from the diffused hardness of ordinary inflammation and the elastic semi-fluctuating sensation given by gland growth as found in lymphadenoma. This diagnostic sign is by no means constant. Lymphadenomatous glands may be hard, and scrofulous ones soft, but the converse is usually found. The diagnosis between scrofulous glands and lymphadenoma is often more difficult than that from simple adenitis; there are some cases which seem to lie between the two. Take the following. A boy, the son of a scrofulous father, has a gland swelling in the neck, very elastic, fluctuating, and free from any inflammatory symptoms. This mass is excised, and is found to consist of quickly growing gland tissue, free from inflammatory or scrofulous deposit; fresh glands grow again, and are a second time excised, presenting the same character; for the third time a gland has enlarged. This boy has had the excessive anæmia which attends lymphadenoma; the glands excised presented the appearance of lymphadenomatous glands, but there is no general infection of glands and no splenic enlargement. I look upon this as a case of lymphadenoma, or as one which was tending in this direction; at the same time, I think this boy will get well, the return each time having been slower, and he is now improving in health; the present gland is, I believe, one which was left behind at the last operation.

General infection of glands, or more than one centre of infection, generally indicates lymphadenoma, but it is not always so. I have a patient from whom I excised scrofulous glands which had undergone cheesy degeneration, and were typically scrofulous, from both groins and both sides of neck and armpits. This patient has no anæmia, and, except the distribution of his diseased glands, has never had a symptom of lymphadenoma. Then, I think, occasionally in the more chronic forms of lymphadenoma that the affected glands may undergo scrofulous degenerations. I had a man admitted into the infirmary in a hopeless condition. He was suffering from lymphadenoma in an advanced stage, and had enlarged spleen and general gland disease. He was too bad for any operation, so that I could not take out the glands to see; but I have no reasonable doubt, from their feel and appearance, that some of his glands had undergone scrofulous degeneration. In mentioning these cases I have used the term "deposit" and "scrofulous deposit," as indicating the cheesy or tuberculous-looking material which is found in scrofulous glands, and as being an expression to which we are accustomed. I do not imply that this matter has been carried and deposited in the gland; on the contrary, it is the gland itself, or a portion thereof, which has undergone this form of degeneration. I have tabulated some of the diagnostic signs which exist between scrofulous glands and simple adenitis on the one hand and lymphadenoma on the other. These signs, however, cannot be taken as absolute. Gland affections merge into one another, and although a fairly marked case of either is distinct and obvious, yet there are cases which lie in the borderland between, and present characteristics which are common to each. Especially is this the case with scrofula and lymphadenoma.

Simple Adenitis.—Gland enlargement is tender and painful, with surface tenderness, and perhaps redness; if acute, is hard and surrounded by inflammatory exudation of the same character. The gland is ill-defined, merged in the general inflammation, and cannot be grasped as a definite tumour. Mischief quickly subsides, either by resolution or suppuration. A distinct and recently acting cause of irritation can be found. No scarring follows.

Scrofulous Glands generally have the pre-existing scrofulous throat, or enlargement follows a catarrhal throat set up by one of the exanthemata. Source of irritation is not generally so recent or definite as in simple adenitis. Glands feel solid, more defined than in adenitis, less so than in lymphadenoma; can be grasped, generally pushed about, are less fixed than in adenitis, more so than in lymphadenoma. Gland less tender than adenitis, more tender than lymphadenoma. Has lasted more than two or three months. Scars follow. Patient has scrofulous appearance or history.

Lymphadenoma.—Patient always anæmic, generally excessively so. Pupils widely dilated. Glands feel and look quite different from scrofulous glands; they are much more

Digitized by Google

numerous, are more rounded and regular in form, are not inflamed, nor are they surrounded by inflammatory deposit. They are very movable, and are to be found in more than one part. The disease extends as a blood disease, and not by continuity. Glands feel elastic and fluctuating. If enlargement of spleen, diagnosis is definitely settled.

It will be convenient here, before going on to treatment, to indicate the various physical conditions in which scrofulous glands may be found. As to consistency, we have the following varieties—1. Soft elastic gland growth without deposit or trace of inflammatory action. 2. Gland growth harder and less elastic; occasional patches of caseous or tuberculous degeneration; traces of inflammatory action. The degeneration may present a spotted or punctuated appearance, similar to, but not so defined as, miliary tubercle. 3. Glands hard and gland tissue degenerated, and generally caseous; correspond with dry gangrene. 4. Glands suppurating, either infiltrated with purulent matter and remaining firm, or caseous matter becoming liquefied, dissolved in pus, soft, and forming an abscess. 5. There is a form of necrosis of gland which happens when rapidly enlarging glands are the subject of active inflammation; sometimes the whole gland dies *en masse;* this form corresponds with acute gangrene. These cases are acute, attended with high temperature and symptoms of blood poisoning. There is every grade between this and the most chronic form. 6. Calcareous degeneration.

Then as to mobility: 1. Glands are loose, and can easily be hooked out by the finger, capsule included. 2. Glands fairly loose, but not sufficiently so to be turned out with the capsule. If, however, the capsule be divided, the gland substance can be slipped out of the capsule unbroken and perfect in form. The capsule in this instance is thin, and collapses. 3. Gland with capsule can be removed with occasional touches of the knife. 4. Capsule adherent, and requiring close dissection all round. 5. Gland capsule indistinguishable, involved in and blending with surrounding tissues and inflammatory material. Thus this capsule may vary from a gauzy film to the thickness of shoe-leather; the gland itself ranges from jelly to cartilage and from cream to chalk. The glands may lie loose or be absolutely fixed, and one may get a mixture of these conditions in the same case. Scrofulous glands affording infinite variety in their form, course, and duration, scarcely any two cases are exactly alike in all their detail. This variety calls for some modification in the treatment, but that treatment only can be successful which will fulfil two requirements—viz., to establish the general health, and to remove thoroughly and entirely the local disease. Firstly, as regards the general health, nothing does so much good as sea air, and plenty of it. The patient should be out of doors all day and in all weathers, and this applies to the winter as well as the summer. With this, generous diet, wine, cod-liver oil, iron and quinine, light, warm, woollen clothing, sponging and rubbing, sea-bathing, avoidance of fatigue and brainwork, amusement, plenty of sleep, large, airy rooms, and everything that tends to make life happy and comfortable. Drugs, except the ordinary tonics, are valueless; no drug will remove tuberculous deposit or get rid of a scrofulous gland that is once steadily established. I have never seen a single case of scrofulous glands cured by drug treatment. Small doses of perchloride of mercury will diminish scrofulous glands up to a certain point by reducing surrounding inflammatory deposit and improving the condition of the less involved portions of the glands themselves, but it goes no further, and I know of no other drug which will do as much; it will not remove scrofulous deposit.

Iodine and its compounds have from early times had a great reputation for absorbing scrofulous glands. How it got this reputation I do not know; perhaps because it is obtained from sea-weed, and sea-air has undoubtedly been found beneficial. I have used iodine internally in large quantities and in a great number of cases; I do not know if it is injurious, but it certainly does no good. Iodine externally in the form of paint keeps up irritation, damages the skin, and does nothing but harm. Iodide of iron has a great reputation; this drug is more prone than most tonics to upset the stomach, but I have found no other effect. Arsenic and sulphide of calcium I have also tried largely without experiencing any beneficial result. In fact, drugs, except general tonics, are valueless, and I think that anyone who has been in the habit of excising scrofulous glands and of examining them after removal must realise this.

The local disease can only be got rid of in one way, and that is by mechanical means; an opening must be made in the skin and the diseased glands either scooped or cut out. Injecting glands with various agents I look upon as an uncertain and dangerous proceeding, especially for those which are deeply seated. One of my predecessors at the infirmary adopted this plan many years ago, but it was abandoned as useless. Nature's method of getting rid of the peccant material by suppuration is a mechanical means; she washes it out by the aid of pus obtained from the gland itself and from the surrounding tissues, but she often leaves behind the stuff she wants to get rid of. It is a clumsy, tedious, and uncertain process, and, even if successful in the end, generally extends over several years. Besides, there is the risk of further infection from these glands going on all the time. That Nature takes a long time is quite certain; if one comes across an adult carrying marks of old scrofulous gland ulceration, the answer to the inquiry as to how long he suffered from the glands is generally the same—viz., "Off and on for years." I have operated in cases that have been extending over twelve, seventeen, and even twenty years.

(To be concluded.)

AN ESSAY ON THE

FUNCTIONS OF INDIFFERENT CELLS IN THE HUMAN ORGANISM.

BY JAMES DICKINSON.

(Continued from p. 586.)

THE instances already given in support of the view that inflammation is a function designed to effect débris removal are insignificant in comparison with the striking instances which exist in the working of the normal body of the function of leucocytes as carriers. It is now generally admitted that the conveyance of food particles such as fat globules from the alimentary tract into the absorbent channels is effected by the agency of amœboid cells. The wide distribution of lymphoid tissue throughout the alimentary tract, and especially in the villi through which solid particles are chiefly absorbed, is of striking significance in this connexion. That the cells of the epithelial lining of the intestine play also an important part can hardly be doubted, since food particles have been seen in their interior. They cannot change their position, but it is quite conceivable that they retain sufficient of their old amœboid powers to enable them, first, to lay hold of particles; secondly, to transfer them through their substance; and lastly, to eject them at their bases. All this could be effected by an intracellular amœboid movement, affecting only portions of, and not simultaneously, the whole cell. Moreover, it seems to me highly probably that the prime agent in first seizing hold of particles is that striated border which has wrongly been called cuticular. It has been suggested (Quain's Anatomy) that this is the morphological equivalent of the bunch of cilia which some other cells of the columnar type possess. The suggestion is valuable. Cilia are filaments of sensitively contractile protoplasm; the old amœboid contractility is retained by a certain portion of the cell for a definite object. It seems to me extremely probable that the striated border is not only homologous, but closely analogous to the bunch of cilia—namely, that it is a certain portion of the cell retaining the amœboid character to supply a need which is here obviously present. It is certain that the striated border is sensitive protoplasm and not "cuticle" as has been supposed—a supposition which might well keep the process of absorption shrouded in mystery.

In studying the amœboid character as it is exhibited by elements in the human body, it is interesting to observe that, while the character belongs *par excellence* to leucocytes, some cells retain a modified degree of it, some have even specialised upon it, while others that have recently lost it are capable under suitable conditions of recovering it. Thus, if the above views are correct, the epithelium of the intestine exhibits a modified amœboid character consistently with retaining its connexions and serving its epithelial function of forming a surface. Again, in the

Digitized by Google

process of digestion, it is observed that liver cells become loaded with particles, fatty and otherwise, and it is difficult to understand the fact unless we credit these cells with a sufficient power of changing their form to enable them to seize upon particles brought within their reach. That some cells have specialised on the amœboid character is seen in the so-called myeloplaxes—those giant cells which are undoubtedly concerned in the absorption of bone. They occur in a tissue distinctly lymphoid—i.e., the marrow; and one is strongly tempted to regard them as leucocytes that have given up their migratory in the special cultivation of their devouring habits. And one is the more inclined to this view from the fact that leucocytes, under some circumstances, are capable of becoming individually hypertrophied. It would seem that giving themselves wholly up to absorption and the destruction—i.e., digestion—of what they absorb, their protoplasm grows under the stimulus of the excessive nutriment they ingest, and division, which is the check upon undue growth, falling also into abeyance, or at most affecting the nucleus, they become the giant cells we are familiar with. Even in circulating blood leucocytes are found possessing several nuclei (Quain). Lastly, just as leucocytes may be observed under suitable conditions to take the first step in organisation, and form a connective tissue, so connective tissue cells may, under the conditions that are present in the early stage of inflammation, undergo retrogressive changes, and resume their old amœboid character.

Crediting the epithelium of the intestine with the limited amœboid powers I suggest, the process of food absorption becomes simple and intelligible. But at this point a question invites answer in order to complete the account of the part played by leucocytes. How do the particles conveyed by leucocytes into the absorbent channels become set free again as we find them in the "molecular basis" of chyle? It is stated in Schäfer's Essentials of Histology that the lymph corpuscles, having reached the absorbent channels, there undergo disintegration, and so discharge their contents. In the same book is figured a preparation taken from the intestine of a rat killed during digestion, and leucocytes are there seen losing their distinctive outline and becoming blended with the fluid and granular contents of the lacteal vessel. This observation prevents us from resorting too readily to the more simple explanation that leucocytes set free the particles by amœboid activity. Indeed, the only reason that suggests itself why leucocytes should ever give up particles they have been at pains to take into their bodies, is that the particles turn out to be indigestible or injurious. Certainly it is equally obscure why they should undergo disintegration, but there is no gainsaying an observed fact. However, one cannot help suggesting the qualification that the disintegration must be merely a cell disintegration, and not a disintegration of the protoplasm itself; for it is hard to believe that the absorption of every particle or so is to cost the life of a cell. Is it not conceivable that the cells disintegrate and the protoplasm continues living and capable of reaggregating into a cell mass as in the case of the "free-cell formation" which is observed in plant life?

Not to dwell longer on this matter, I may just point out the broad fact that is beyond controversy—namely, that leucocytes do in the normal process of absorption of food serve a striking use as carriers of material. Another striking instance is seen in the transfer of particles from the air cells of the lungs to the neighbouring lymphatic glands. Leucocytes are admitted to be the agents by which this is effected. Doubtless, in this they are serving a definite function—probably that of removing irritating particles from the delicate surface of the air cells. Natural stomata exist which open from the air cells into the lymphatic spaces of the pulmonary tissue, and, since amœboid elements are commonly found free in the air cells, the conclusion seems to be fair that they have normally ingress and egress through the stomata for the purpose of keeping the air cell clear. But probably a more serious duty is theirs than the removal of mere inorganic particles, and that is to seize upon and kill by intracellular digestion all micro-organisms that present themselves in inspired air. This view has been advanced in order to explain the general immunity from those specific diseases whose micro-organisms are widely distributed, and I do not doubt that this is the most important function served by the diffuse adenoid tissue in the respiratory tract. A similar protective function must be added to the absorbent function served by adenoid tissue in the alimentary tract.

Enough evidence has been brought forward that the picking up and carrying off of particles is an accomplishment of leucocytes by no means assumed for the delectation of microscopists, but natural to them wherever they may be, and serving indispensable uses in the normal economy. Surely it can no longer be doubted that this is the use they serve in inflammation. This view renders it at once intelligible why the entrance of micro-organisms into a wound should be associated with suppuration. Not only must they be destroyed and removed as foreign bodies specially inimical to local repair, but they must be prevented from gaining an entrance into the organism at large. Thus pus cells are but leucocytes that have died at their post in the execution of an essential duty. There is a disease known as leucocythæmia, of which the striking anatomical feature is an enormous increase in the number of leucocytes in the body, evident both in the naked-eye appearance of lymphatic tissue and in the microscopic appearance of the blood and lymph. In the subjects of this disease repair of wounds is very imperfect, and attempts at organisation of inflammatory exudation abortive. At first sight this would appear to be inconsistent with the present view of the usefulness of leucocytes in inflammation. But it is found that the vitality of leucocytes in leucocythæmia is particularly feeble. They do not exhibit amœboid movements or any of the active characters of leucocytes in healthy organisms. By the light of this observation the failure of tissue repair in the subjects of leucocythæmia is seen to be consistent with the view under consideration and confirmatory of it; while the occurrence of an excessive number of leucocytes as a feature of the disease suggests itself as an effort to make up by numbers for individual incompetence.

But granting that inflammation is a useful process that meets a pressing need, why does it take place? How do the leucocytes know that they are in request that they offer themselves so promptly? We have seen what is the need that exists when inflammation occurs; we have seen how inflammation meets that need; it yet remains to be seen how an injury while causing tissue-damage gives rise to a process which leads to repair of that damage. Michael Foster, in his Text-book of Physiology, describes the vascular phenomena of inflammation, but says not a word to imply that any active part is played therein by the leucocytes themselves. He treats the bloodvessels as the sole agents in the matter and offers his picture of the process as an illustration of some mysterious power he believes the vessels to exert over their contents. We may remind ourselves that the phenomena are mainly these. First an increase in that normal distinction between axial and plasmatic layers, the leucocytes loitering in the area affected and gathering along the vessel walls, while the red cells pursue their axial course. The leucocytes continue to gather till they are thickly aggregated upon the lining of the vessels. Then little processes appear upon the outside of the vessels belonging to leucocytes within. These processes grow while the leucocytes to which they belong diminish till there is complete disappearance from within and reappearance without. Then their connexion with the vessels becomes severed and they are at large. Now Foster says, and I quote his words: "It seems probable that the aggregation in inflammation of the white corpuscles upon the lining membrane of the vessels is due to a special attraction which the bloodvessels exert on the white corpuscles." A more satisfactory explanation is that the leucocytes are themselves the active agents and that the walls of the vessels, though essentially concerned, may be compared to the damaged bars of a prison that allow a captive to get out. Is it to be supposed that leucocytes lose their power of independent locomotion while they are circulating? Certainly not. What is so noticeable in their demeanour as they are seen coursing along in the blood stream? It is that they are not carried helplessly like the inert red cells, but exhibit some independence, feeling their way, as it were, along the wall and stopping now and again. This has been accounted for by their "peculiar adhesiveness." But why not account for it and for their peculiar adhesiveness at the same time, by crediting the white cells with some independent agency in the matter? Their behaviour within the bloodvessels is so extremely suggestive that they are trying the walls of their prison as they proceed, and seeking a way out. What, then, more natural than that when they come to a place where the vessel wall is damaged they should succeed in their endeavour? I use the word "damaged" provisionally without in the least intending to describe the

Digitized by Google

change which the vessel wall has undergone. Whether injury be the direct cause of the change, or whether (as seems probable in cases where inflammation has supervened without traumatism) there is some obscure physiological connexion between the cells and the bloodvessels of a tissue, we are fairly safe in describing that change as "molecular." At all events, it probably means some impairment of vitality, and one can distinguish two ways in which this would favour the escape of leucocytes. For impairment of vitality involves loss of elasticity, which must lead successively to increased resistance to flow, dilatation, and stagnation, which last obviously encourages any attack the leucocytes may attempt upon the wall. Again, loss of elasticity must involve relaxation of any stomata which the leucocytes may have discovered or have made by the insinuation of pseudopodia. Such a view of the process of migration is more conceivable and rational than one which refers it "to a special attraction which the bloodvessels exert on the white corpuscles." For this entails certain difficulties. It is, in the first place, not easy to see why injury should suddenly inspire the wall of the vessel with a special attraction for the white cells, selecting them, moreover, in preference to the red. One has next to get over the difficulty that the leucocytes get over when they are half way through, for it might reasonably be expected that a "special attraction" would hold them fixed in this awkward position. Lastly, we cannot but wonder what becomes of the "special attraction" when the leucocytes, having effected their passage, break away from the vessel.

I said in the early part of this paper that I interpreted inflammation as an exaggerated manifestation of a normal function, and that when we had determined the function of inflammation we should have found the clue to the, or at all events a, function generally served by leucocytes. We have seen leucocytes serving special functions in the alimentary tract, and in the respiratory tract as carriers and scavengers—functions both allied to what is believed to be the function of inflammation. But in the respiratory and alimentary tracts the functions of leucocytes are special and concern only those two situations. Inflammation, however, may occur anywhere, and what has now to be shown is that, no matter where it occurs, it is an exaggerated manifestation of a process normally going on at that spot—that is to say, it has to be shown that the migration of leucocytes from the vessels into the tissues is a constant physiological event, and that the function served by these leucocytes is the removal of cell débris. It may easily be proved that leucocytes habitually migrate from bloodvessels. Remembering their roaming habits, and remembering their demeanour in the bloodvessels, and remembering the stigmata that exist in capillary walls, and the power, further, that leucocytes possess of insinuating pseudopodia, and then flowing along the narrow isthmus so formed, we seem to have good reason to believe that migration may normally occur by such a mechanism. But we have absolute proof that it does occur. In course of digestion the number of leucocytes in the blood increases considerably. This is understood to be due to the vigorous lymphatic circulation which accompanies absorption at the lacteals, leucocytes being thereby carried into the veins of the neck from the lymphatic system where they chiefly abound. But some hours subsequently the number of leucocytes in the blood is found to be the same as it was before the meal. Rejecting the view that leucocytes are split up in the blood to provide food for the tissues, the conclusion is inevitable that they have escaped from the blood-channels. The only ways open to them are back into the lymphatics against the current or out through the vessel-walls into the tissues. We need hardly consider the former alternative and are driven on to the latter.

(To be concluded.)

SOCIETY OF APOTHECARIES OF LONDON.—The results of the examination in Arts qualifying for registration as medical student, held in the Hall of the Society on Sept. 6th and 7th, have just been published. There were 155 candidates, and from the pass-list it appears that 3 were placed in the first class, and 18 in the second class, and 114 were certified as having passed in some subjects, but not in all. The next examination will be held on Dec. 6th and 7th, 1889, and again on March 7th and 8th, 1890.

A UNIQUE CASE OF FRACTURED EXOSTOSIS.[1]

BY THOMAS H. MANLEY, M.D.

THE case on which this article is written presented many features quite peculiar to itself, seldom heard of, rarely dealt with, and probably seen only occasionally even in the practice of those of very extensive experience. For, being of an extremely obscure nature with respect to its real character, for the many and unusual coincident pathological conditions, the odd and singular form of this bony excrescence, as well as the surgical measures adopted for its removal, it would seem to stand nearly alone.

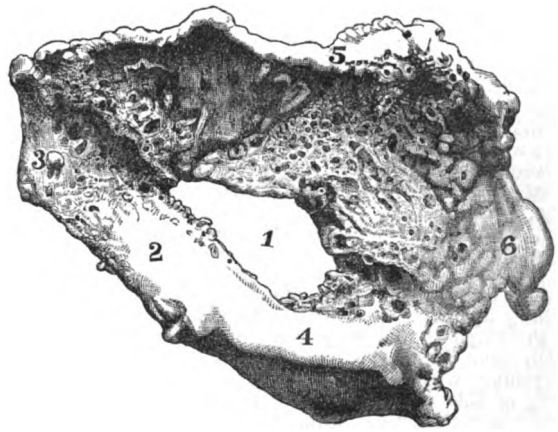
Our patient was a young Italian, nineteen years of age. He had been in America two years, and had always enjoyed good health until a little more than a year previously, when he said he commenced to feel slight pains along the inner side of the leg, which, though severe occasionally, at times would annoy him but very little. During one painful spell he consulted a physician, who treated him for rheumatism. He had finally become so accustomed to the difficulty that it gave him little thought, till one day, while working with other labourers in excavating a drain, in making an effort to raise a heavy piece of stone he suddenly became weak, and had to desist from work. This weakness was followed by chills and pain all over the left lower extremity. After remaining away from work a week he returned. He now found himself lame and only able to continue at his occupation with considerable discomfort. He soon had to stop again, when he applied at the hospital for admission. This was sixteen days after the mishap in the trench, and about a year from the date that he first felt anything wrong on the same side. He walked to the hospital—about half a mile—and readily ascended a couple of sets of stairs without any assistance.

Condition on admission.—He was extremely weak, very much emaciated, very pale, with the look of one in much distress. How he was able to drag himself to the hospital was a marvel to all who saw him. His pulse was now nearly 120 beats per minute, with a temperature of 101°. No evidence of organic disease was found. On being stripped of his clothing, the left lower limb was seen to be greatly swollen from Poupart's ligament down to the knee, mostly on the inner aspect; though the outside was also considerably distended, but to a lesser degree, in the same direction. Now, the question was, What could this great increase in volume be attributed to? Was it a hæmatoma, an osteoid-sarcoma, a simple serous accumulation due to blocking of the deep femoral vein; or was it an accumulation of pus? As there was no history of injury, either recent or remote, we were led to eliminate rupture of a vessel as a cause; and as there was good circulation in the vessels of the limb lower down, which would not be the case if directly dependent on vascular lesion, we were led to believe that pus was present. This was decided beyond question by the exploring needle. It was clear that there was an enormous formation of purulent matter; but when we came to consider the question as to its probable origin and exciting cause, we were obliged to hesitate. There being nothing pointing to traumatism, and no trace or signs of vertebral disease, and the chief symptom being of recent date, it was rather difficult to reach a definite conclusion. Had he been laid up any considerable time in bed, it would have led us to suspect an abscess of the psoas variety, or that there was bone disease involving the hip-joint or upper part of the femoral shaft; but with a man walking into hospital unaided, the existence of any of these lesions seemed impossible. Regardless, however, of what or where the real seat of this pus was, the indications for treatment were very plain. The first was to open into the matter and drain it away; the second, to endeavour to find its exciting cause, and if practicable remove it. It was hoped that with a free vent for the abscess and free irrigation of the parts with some mild non-irritating antiseptic solution, our patient would soon recover; remembering that for some cause not yet well understood, especially in erysipelas, pus will form in enormous quantities in the deep loose areolar tissues; and also, in what was formerly designated

[1] Read before the Amer. Med. Assoc., Newport, R.I., June 25th, 1889.

Digitized by Google

cold abscess, in those of strumous taint. Our patient consented to permit us to make an opening, but not do any severe operation. To do anything else at that time in his condition would have been unjustifiable.



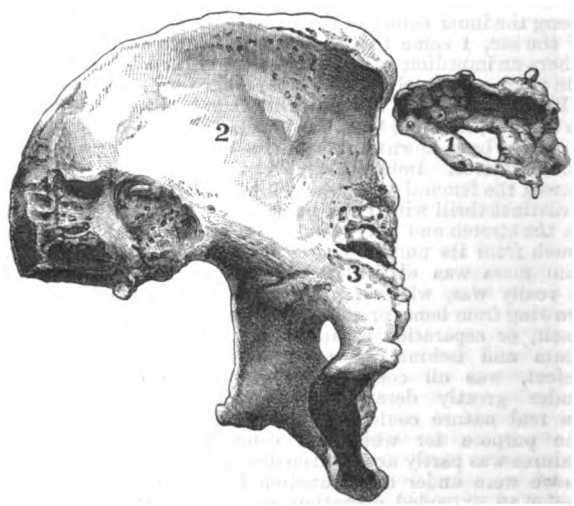
After putting him under an anæsthetic, a free incision was made over Scarpa's triangle, at its apex, carrying it downwards about four inches. Immediately on division of the skin, an immense tense sac bulged into the opening made by the scalpel. Now it was evident that something of a most unusual character was in our way. Accordingly, with a view of making an opening large enough to manipulate and explore through, the incision was slightly enlarged upwards, and the superficial and deep fascia lata divided, separately with the scissors. The pus sac—the pyogenic membrane—was now drawn as far outwards as possible, and opened. Pus, of the consistence of cream, poured through the orifice. It seemed to come from every direction when pressure was made over the quadriceps tendon; over the popliteal space, the groin, the loins, the pubes, and even, when firmly applied, over the abdomen itself. It was at once evident that the accumulation had extended into and invaded all the adjacent tissues. In passing the fingers into the wound with a view of estimating the extent of pyogenic membrane, and the course it pursued, it was plain that it had insinuated itself above and beneath the floor of Scarpa's triangle; that it had displaced the sheaths of the hamstring muscles, pushing away from the bone the femoral vessels in the lower part of the thigh, and burrowing under the sciatic nerve so that it could be readily defined under the fingers. The pyogenic membrane was of the sacculated variety. It was very thick and tough; where the knife penetrated it seemed as dense as the integument itself. Following up along the inner border of the sartorius muscle in the lumen of the sac, I came to the horizontal ramus of the pubes, where an impediment was encountered of a kind which, for the time, completely baffled us to make out. It was lodged a little to the left of the centre of the pubic body. It seemed as large as, or larger than, the hand, of a sort of conical form, with its base downwards and its apex pointing upwards and outwards. Immediately over the summit of this cone passed the femoral artery, which transmitted to the fingers a distinct thrill with each pulsation. The artery was put on the stretch and lifted out of its bed, and deflected very much from its normal course by this body from beneath. The mass was distinctly but slightly movable. What it really was, whether a neoplasm of osseous formation growing from bone, or whether it was a fracture of the bone itself, or separation at its epiphysial junction with the ilium and ischium, perhaps attributable to congenital defect, was all conjecture. It was so deeply buried under greatly deranged and infiltrated tissues that its real nature could not be accurately made out. As the purpose for which we commenced operative procedures was partly accomplished—the removal of pus—and as we were under an injunction from the patient not to make an extended operation, we desisted from exploring any further. Drainage-tubes were inserted, and the whole put up in antiseptic dressings.

After putting our patient in bed and supplying every comfort at hand, time was permitted to study the case and devise some method by which an operation for the removal of this substance could be accomplished. I had decided not to undertake any further operation without the advice and assistance of Professor F. S. Dennis, the senior visiting surgeon, as I fully appreciated that there was a case before us of a kind on which we could get but little light, either as to its true character or the way to safely remove it, from the ordinary available surgical literature; it being one of those cases which now and again turns up in which we are thrown on our own resources, when we must depend on our own knowledge of the laws of pathology, anatomy, and our own ingenuity. He immediately improved after evacuating the pus. The temperature went down to normal, and for a few days he gained strength. Unfortunately his improvement was but transient; pyæmia began to manifest itself, and we found that no longer could delay be permitted.

What we had to remove, and how to do it, were the questions we now had to face. It seemed hardly credible that it could be the fractured or separated pubic bone; for it would seem, with the point of attachment and origin of leverage of all the adductor muscles and those composing the inner hamstring broken off, that locomotion would be impossible, though we all well know the remarkable compensatory action which certain groups of muscles possess. It did not seem impossible either that, with the gluteal muscles, the rectus femoris, and those coming from the pelvis, the head of the femur might be retained firmly in position, even if little motion could be executed. Professor Dennis advised and assisted me in the operation for excision. I may say that without his generous aid and wise counsel we would very likely have failed in our efforts. How were we to proceed in the displacement of this huge mass without either opening into the parietal peritoneum or impairing the integrity of Poupart's ligament? To touch the peritoneum with the taint, infecting almost everything in the region of the wound, would be certainly fatal. The great artery of the lower limb with the femoral vein were in danger of laceration or division, as we would be obliged to draw the mass from under them and effect their detachment in our manipulations. After very carefully, in anticipation of operation, opening down in this region a few days previously on the cadaver, and considering the different routes by which it seemed most practicable to reach the formation and bring it through, I found that there was but one way in which it seemed at all possible to remove it, without sacrificing very important structures; and even here it was discovered that we must divide the anterior crural nerve, and possibly be obliged, if the mass was of great size, to divide or crush it with the bone pliers and remove it in sections.

With the plan of enucleation well fixed in mind, and everything in readiness, so that we might deal promptly and effectually with any unexpected accident, we commenced an operation for a condition of which I can find nothing exactly similar in surgical history. The original incision was extended along the sartorius, till its origin was reached, when the psoas muscles were found and drawn well over, towards the acetabulum, from the vessels which passed directly over them. Now these muscles were divided in a vertical direction, their sheaths opened and their fibres separated. We found that they in the process of time, from excessive pressure from below, had thinned and spread out, like a broad ribbon, and seemed to extend over the greater part of the osseous body underneath. This step of the operation was attended with considerable danger, and the greatest caution had to be exercised. The retractors were now inserted, and the bloodvessels pressed gently towards the symphysis, and I was enabled to pass my index-finger down on to what I found was bare denuded bone. By introducing the periosteal elevator, and detaching the more or less adherent fleshy tissues, I was able, after a long fatigning effort, to remove the cause of all the trouble; the pubic bone, sure enough. (Fig. 1.) At least, at first sight, its resemblance was so close to that part of the skeleton that we could not well liken it to anything else. It was structurally identical to this portion of the skeleton. It had the same shape, the two rami, the ischium attached or fused with it below; the tuber, to which all the hamstrings are inserted, preserving its normal contour and position, the obturator foramen being of the same oval outline as usually met with. When this bone then was raised from the pelvis, we certainly concluded that it had separated from the acetabulum, either through disease, faulty original development, or from an acci-

FIG. 1.



Digitized by Google

dental fracture. In the course of removal there was unavoidably considerable mutilation, and it was found impossible to proceed without the bared lacerated muscular tissue coming in contact with the extensive purulent material, which seemed to issue from every direction. In the meantime everything was done to avoid the contamination of healthy parts. The bichloride solution was freely applied for the purpose of washing out and neutralising any septic taint which might linger in the deep tissues. Drainage-tubes of various shapes and sizes were introduced, and counter-openings made, so that the whole tract of the wound could be effectually treated. The usual antiseptic dressings were applied, and the patient returned to the ward. He rallied very slowly, the effects of the shock persisting a considerable time. The morning following the operation he was much improved, the temperature being but slightly elevated, though the pulse remained weak. He seemed to gain until the fourth day, when pyæmia again declared itself, with well-pronounced symptoms. Meanwhile every day the wound was dressed. Pus came away in enormous quantities, soaking through all the many layers of antiseptic cotton and gauze which enveloped the wound. After the fifth day it became evident that we must lose our patient. He now had a profuse, uncontrollable diarrhœa, with exhaustive sweats, and was in constant pain when not under the influence of opium, and on the evening of the tenth day passed quietly away.

It fortunately so happened that we were permitted to make an extensive and very careful examination post mortem. Strange to say that, notwithstanding his severe illness, he had emaciated but little. A most casual examination now showed conclusively that though we had removed a pubis and ischium, the whole of the pelvic skeleton—the whole of the left wing of the ploughshare, as anatomists designate this bone—remained. If one had been removed, it was clear that another remained. Turning our attention to the limb, to the line of incision, we found that though the silk sutures still held the edge of the wound together, there was no attempt at union. Everything was pus-soaked. Between the different layers of fascia and the muscle sheaths, extending down to the terminus of the biceps, a large, broad, thick, pyogenic membrane was now to be seen, with its dense tough walls, externally adherent to everything which came in its way—at one point, reaching out and engaging the sheath of the large vessels, and at another firmly adherent to the floor of Scarpa's triangle, pushing up and away from it the rectus and fascia lata. In the thigh it had very many well-defined diverticula, which seemed to have bored themselves into and through everything which came in their way. The internal lining of this sac was smooth, though with an irregular surface, not altogether unlike the serous lining of an artery. Finding that it had crowded the various groups of muscles in the ham in every direction, we now followed it towards the body, presuming that its limit would be reached at the seat of the original trouble, on a line with the pelvic brim; but we found the pathology of this case as inexplicable and puzzling as its clinical history. Arriving at the crural arch, we stopped. Now, after removing the pelvic viscera, which we found healthy, we continued our exploration upwards. This strong leathery pus sac, after entering the pelvis to the inner side of the pubic bone—its horizontal ramus,—was now traced upwards, behind the peritoneum, and between the psoas muscles, up to their very roots, dividing in its upward course into two sacculi, which penetrated the sheaths of these muscles and ended only at their origin; in fact, when it seemed it could go no further. Taking care that there was no necrotic action going on in the bodies of the lumbar vertebræ to account in part for this pus production, they were minutely examined, but with negative results. In the pelvis, as in the limb, diverticula extended in nearly every conceivable course. Pus was found to ooze through the tissues in the line of the femoral vessels, in the opposite limb, along the rectum, and under the floor of the bladder. We now came to the outer and anterior wall of the bony pelvis, in search for the part from which this osseous formation had come. Just anterior and above the acetabulum, directly beneath the anterior inferior iliac spine, and under the iliac and psoas muscles, was a broad, rather circular-shaped stump of bone, showing evidences of recent cleavage. This stump or stalk had a broad regular base rising directly from the horizontal ramus. Its fracture was about half an inch from the pectineal line, and took an irregular oblique direction. It was entirely stripped of periosteum till the body of the pubes was reached, when this covering was intact. I now removed the entire os innominatum. The body being not yet matured, the sacro-iliac junction was easily divided with the knife, and I here exhibit it. (Fig. 2.) Nothing of special interest was found in the organs except the lungs, where the typical infarctions of pyæmia were seen in abundance.

We had at last, after many conjectures and aimless gropings, been able to determine without question, by indisputable proof, what our patient's affection was; but, alas! we were unable to save his life. Now that death enabled us to clear up all doubts, we come to that part of his history replete with interest and well worthy of a full consideration. I refer to what the probable origin of this formation was, which though possessing many of its characteristics in its clinical history was not a neoplasm. While being a mere typical, innocent substance by its situation and an accident, it ultimately became a cause of death. I think we may ask ourselves, were its true nature, shape, and position known, and the treatment accordingly adopted, might not this young man's life have been saved? For some time after my patient's death I revolved in my mind the causes which might have acted towards giving this osseous outgrowth its strange similarity to the pubes. I reasoned that it could not be regarded as a merely fortuitous development, that it could not have so adapted itself by pressure, exerted through muscular action. While quite perplexed to account for it, and nearly despairing of ever being able to give a rational explanation for its existence,

FIG. 2.

I one day, about a month after the death of the patient, was narrating a few of the interesting features of the case, and showing the specimen, when my friend Dr. James O'Brian of New York, on getting the bone in his hand, pronounced it "a genuine case of reduplication of the os pubis." He further said, "it was his opinion that the production, this precocity of nature, was of congenital origin, that it had existed since birth, and that it was only when perhaps disintegrating from imperfect nutrition it gave way and became a foreign body." My friend O'Brian's opinion of the matter struck me as so simple and rational that it could hardly be questioned. If we can have supernumerary fingers, members, and organs, it seems quite reasonable to suppose that the same freaks of nature may extend to the pelvic bones. It occasioned trouble only when detached; when it became a source of irritation. Had we clearly comprehended its nature at the outset, its management might have resulted in greater success. I believe if we had aspirated off the pus a little at a time and kept the cavity of the sac well aseptic, besides watching his general condition and keeping him well nourished until his strength was restored, we might have removed the reduplication or exostosis with every prospect of success. But in opening up a way to bring the bone through healthy tissues were unavoidably infected. The pyogenic membrane was a most remarkable pathological production, both for its extent and thickness, as well as beautifully illustrating the conservatism of the economy

Digitized by Google

in placing this barrier between the sound and diseased parts; covering, confining, and limiting the diffusion of pus. It, besides, showed how completely and effectually purulent material may be walled in without there being any pronounced symptoms or serious constitutional disturbance present to indicate its existence. It may, I think, be asked in closing, as this was a benign formation destitute of any malignant elements, if left alone might not the result have been different? I think it might. In time this diffusive abscess would no doubt have pointed, thinned the skin in its course towards the surface, formed firm adhesions in its way through, and opened spontaneously without in any way contaminating healthy tissues, the sac gradually undergoing contraction, thinning, and absorption, until at last the economy, having no further use for it after the exostosis had come away and thrown off the last vestige of matter it contained, would quickly and entirely dissipate it. As it was, every reasonable precaution was taken, but owing to the obscure character of the condition existing a correct diagnosis was nearly impossible, and we were obliged to deal with difficulties as they arose.

New York.

REMARKS ON

THE WANT OF KNOWLEDGE OF MENTAL DISEASES SO PREVALENT IN THE AVERAGE MEDICAL MAN.

BY GEORGE THOMPSON, M.D.

I WOULD gladly adopt the suggestion made in the editorial annotation on "Bromomania," contained in THE LANCET of May 25th, to substantiate the charge which I make in a former article (on the "Hospital Treatment of the Insane") of ignorance on the part of medical practitioners of the ordinary diagnosis and treatment of insane persons, but for two reasons: the first being that I should be compelled to fill many pages of THE LANCET with matter which would not interest the general reader; and the second, that I should empty the coffers of the treasury of this journal by the number of actions at law which its proprietors would have to meet. I will therefore confine myself to a recital of my very own experience of the facilities which were at my disposal as a student in medicine for learning anything whatever about insanity. There is no law which would enable me to bring an action for libel against myself, and so I proceed to my task heedless of results.

I passed through the usual curriculum, and obtained the diploma of M.R.C.S. in April, 1867. Up to that date I had never had the subject of insanity brought to my notice, except in this way: the lecturer on forensic medicine, the late Dr. Pyemont Smith, kept a very select private asylum at Ilkley, in Wharfedale; but he never mentioned the subject in his lectures. A fellow-student and I (we were both medical superintendents in a very embryonic stage, but we did not know it) agreed to ask Dr. Smith if he would allow us to see his asylum. This request he most courteously granted, and fixed the day. We went, and found the asylum was a fine old mansion high above the Wharfe, and commanding one of the loveliest views in the world. It was licensed for fifteen patients, and that was about the number we saw. Some were sitting or lolling on the terrace, some reclining in chairs in the rooms, and one was in bed. Dr. Smith, most properly, never said a word about the patients (private asylum doctors never do); but I have never forgotten that first lesson, which taught me that insanity, like (as Lytton says) love and death, is a terrible leveller. The patients were all of the higher class, probably persons of good position from Leeds, Bradford, and other towns near. They were most decidedly of the class which is called "quiet" and delights the heart of every private asylum keeper, for they give so little trouble, and are therefore proportionately profitable. I have never seen such a sight since—such wrecks of humanity; I daresay it was the novelty of the scene which struck me. As I think of that sight at this remote period of time, I cringe when I think how the acute cases which now are under my treatment may pass into secondary dementia, because of our frequent helplessness to avert the onset to such a state. That was the first and only lesson I had when I was a student.

But after I became M.R.C.S., and before I joined the staff at the West Riding Asylum, I had another lesson which was equally striking in its effects, though in a different way. I was attending a labour. The two women present to assist were talking, and this was the dialogue: "What became of Sally Jones?" "Oh! she went to Wakefield Asylum." "What happened to her there?" "Oh! she soon died." "Why did she die?" "Oh! she got so bad that they put her between two feather beds, and six keepers sat on her and smothered her." Of course, I sat with the usual gravity of manner and made no remark. The lesson I learned was that there still prevails an idea that the inmates of asylums are done away with. However, I cannot but admit that that would be an excellent way of avoiding "secondary dementia." But, then, I was in possession of a diploma, which I had but to put on the Medical Register to become "duly qualified" in every sense to join in a conspiracy, as has been playfully (I hope) suggested, to deprive a fellow-creature of his liberty, perhaps for life; and this was the amount of teaching which had by chance been apportioned to me. Now, what was the value of that knowledge to me, who at any time was equally qualified with other average men to give an opinion from "facts observed by myself" and from facts "observed by others"? If the examinee threw his arms in the air and declared that he was a windmill, or that the world was a ship and he was the captain, I might safely have said that he was insane, if he was not shamming insanity. But lawyers say that any man with common sense could say as much. And I think the lawyers are right. But in how many cases does the man not throw his arms about? and then, where does the examiner, as ignorant of insanity as I was, come in? I have heard of a case where the one "fact" was "Reads the Bible"; and frequently see such as "His speech is clipped," "He is awkward in his gait." These are physical defects no doubt, often of serious import, but they are not necessarily facts indicating the inability of the individual to manage himself or his affairs.

But to bring this paper to a close, I think it will be admitted that there is no royal road to the knowledge of insanity. It cannot be learned from books; it must be learned from a "master." Could a boy be trained to be a carpenter by reading books? Of course not. And where is the difference? I had never heard the term "general paralysis" before I went to Wakefield, and I do not hesitate to say that had I read all the books that ever had been written on the subject I should never have got a bit nearer being able to distinguish a case had such a one come before me in private practice. The person who wishes to understand anything about insanity must learn it under a master and must live among it. In many cases the diagnosis is a matter of physiognomy—a *tactus eruditus*,—a knowledge of which can only be got by constantly seeing such cases. A member of my family, who has never had an official or other connexion with any asylum, can look down at the patients at the church or at the dance, and, with unerring precision, point out every general paralytic in view of her. This comes from frequently seeing them. Now a man, even with ever such high medical qualifications, might examine (say) a hundred cases of alleged insanity in a year, among which there would be fifteen or twenty general paralytics, and he would not distinguish one of them, and he might go on for twenty years and he would be in the same condition of ignorance at the end of that time. I cannot remember that I have ever known a case of that sort to have been diagnosed before admission to the asylum. Once a medical man kindly wrote to me about one, and said he thought the patient was suffering from "softening of the brain," and that he had been treated with forty-grain doses of bromide of potassium three times a day, which had "quietened" him, and advised me (how kind!) to continue the treatment! He had, indeed, "quietened" the patient: he had expedited a "desolation" which he mistook for a "peace."

Stapleton.

RABIES.—The number of dogs in England officially reported during the week ending the 14th inst. as afflicted with rabies was 8, against 9 in the previous week. They were all killed. The distribution was as follows: Surrey, 2; East Sussex, 3; West Sussex, 1; and York (West Riding), 2. No cases were reported from London. One horse suffering from rabies was also killed during the week in the West Riding of Yorkshire.

ON ONE FORM OF PUERPERAL ECLAMPSIA.[1]

BY WALTER T. COLMAN, M.R.C.S. ENG.,
FELLOW OF THE OBSTETRICAL SOCIETY, LONDON; CONSULTING SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN, BRIGHTON, SUSSEX.

THE present paper is designed to illustrate the theory of the cause of a form of eclampsia puerperalis—viz., that due to sudden and forcible extension, and consequently stretching of the cervix uteri, thereby inducing convulsions, independently of the albuminous factor, which latter, with the majority of authors, is a *sine quâ non* of the disorder. I am wishful now to contribute a mite of assistance in forming a proper classification of such conditions of the system, and *a fortiori* the most applicable and proper treatment for each division.

The first impression given me of the close connexion between puerperal eclampsia in one form and violent stretching of the cervix uteri occurred in a pluripara, who had had more or less constant hæmorrhage for ten weeks previously to the termination of the full period. She was not my patient, but I was asked by her medical attendant if I would assist him in dilating the cervix, which was very rigid and unyielding, to an extent which would permit his performing version. After two hours' perseverance I succeeded, by careful manipulation with my two forefingers and thumb of the left hand formed into a cone, in opening the os to the size of a circle somewhat larger than a half-crown piece. My friend returned, and, having concluded that he could pass his hand through the aperture, commenced the operation; but as he forced his way through the cervix into the uterine cavity, the patient had one tonic convulsion and died there and then, without rallying in the slightest degree, although galvanism and every restorative at hand was used as promptly as possible.

The second case I had under my own care was that of a primipara about twenty-two years of age, florid complexion and fair, who was in labour many hours with violent uterine pains, but whose cervix was most resistant and cartilaginous. I watched my patient for a very long time, but the neck seemed as if it would not yield. I had not my forceps with me, but having determined to apply them—the propriety of which treatment I now doubt,—I ran to a friend who lived close by and borrowed his instruments. I was not absent more than ten minutes, and on my return I found the head pressing on the perineum and the patient in violent convulsions, which I learned came on a few minutes after I had left the house. Chloroform was given at once, and the delivery accomplished in a very short time instrumentally. She remained in a semi-apoplectic condition the whole night—viz., for about ten or twelve hours,—and when I visited her the following morning her senses were beginning to return. She did well. In this case I must say I certainly anticipated convulsions from the previous jactitation, delusions, and incoherent talking, and other premonitory symptoms which were present. Had I administered chloroform there and then instead of rushing for instrumental aid, I believe I should have saved my patient from the dreadful peril of eclampsia.

My third case is that of a pluripara, who aborted at the fourth month. The following is the history. Mrs. P——, aged thirty-four, a woman of florid complexion, dark hair and eyes, and excitable temper. Says she had three children born alive, the first by instrumental means, and the youngest came into the world naturally sixteen months since. Her periodic times returned seven months after delivery, and continued monthly up to January 10th, when the flow remained on her for three consecutive weeks. She dates her conception soon after the termination of the discharge. She said she was very sick for the first month or six weeks, but not so much as usual. After her primary confinement she menstruated every month during lactation; but it began at the seventh month with her second and third confinements. She now considers that she has been impregnated four months. After an outing in the country ten days since, and a great deal of walking and pleasure seeking, together with a hurried journey to catch the train, she found on arriving home that she had a show which continued daily, but no pains, with the exception of those of menstruation, until last night at 10.30, when their character became more violent and severe, and were followed by a discharge of liquor amnii and some little hæmorrhage. Subsequently the ovum came away uncovered by membrane and placenta. Expulsive efforts caused much flooding, and she had fainted six times before I had visited her at 5.30. Next morning her condition was one of great bloodlessness, being extremely blanched and suffering from collapse and almost pulseless. On examination per vaginam I could feel the os to be occupied by a fleshy mass, which I endeavoured to remove by passing my forefinger round and dilating the rigid cervix, but without success, and with the effect, to my great surprise, of producing eclampsia, beginning with fainting, fixing of the eyeballs, and slight twitchings of the angles of the mouth, and followed by flushing of both cheeks. In fact, the common signs characterising *petit mal*. I discontinued my exertions at once, but on making another attempt in about a quarter of an hour there was a recurrence of the symptoms, and in my various trials to remove the placenta I found a recurrence of the eclampsia also again and again as often as I stretched the rigid cervix. I at last succeeded in detaching the whole substance of the mass and brought it away. Her own description of the attack was that it came on with a singing noise in the ears as of a kettle boiling, and she herself seemed to be some little time in it, although, as far as I was able to judge, it did not appear to last more than a minute. Seen on the following morning, May 21st, says she had a good night, but awoke with pain in the occiput. Has generally had headache the third or fourth day after delivery. Diet, milk taken by the stomach giving ease to the pain, which latter diminished as evening approached.—May 22nd: Bowels relieved; more restless. Movement of head causes a rushing sensation coincidently with cardiac palpitation, the rushing coming on at every throb of the heart, the two seeming to be cause and effect. Lochia very little in quantity. Tongue pale and flabby. Face anæmic. Diet: Chop, bitter beer (four ounces), port wine (three ounces). — 23rd: Passed a very wakeful night, and has much headache, which, as usual, is worse in the morning after the night's rest, and disappears gradually as evening is nearing. Up to the present time she has been taking acetate of iron and chloric ether. I now stopped all stimulants and solids, and ordered simply milk and beef-tea to be given.—24th: No headache, and slept well. The five-grain compound rhubarb pill taken last night had produced an action of the bowels, causing great fainting and pain as motion passed through the rectum. From this period there was gradual convalescence under the ferruginous treatment, combined with the bromide and chloral, &c. I can recall to mind two or three other cases typical of this form of puerperal eclampsia, although I regret to say I have not preserved the notes.

Now two of the three cases I can vouch for not having an albuminous condition of the urine after labour, and if they had previously they certainly did not show any outward indications of the malady. In my first case, which proved fatal, there did not seem to be any of the usual uræmic appearance of Bright's disease, and looking at the state of my first and third cases as closely allied in their character and form, and differing only in degree of cause and effect, and stage of pregnancy, the two important factors in causing the fits were anæmia and stretching of the cervix. In Mrs. P——'s case I could produce eclampsia at will. The second case was one which had a vascular condition, the reverse of the others with the excito-motor system at a very high standard of tension and the violent uterine efforts driving the head through a rigid cervix forcibly and suddenly conveyed the shock to the higher nervous centres and caused the convulsions. As Dr. Barnes says in his lecture of April 12th, 1873, the healthy correlation of resisting power of irritation and nervous energy were not harmoniously preserved, allowing all to work on an orderly circle. Dr. Lever asserts that albuminuria always induced eclampsia puerperalis, and that the latter never existed without the former, dogmas which, I must say, experience teaches me to disbelieve. It is questioned by some as to whether the fit is consequent on the obstruction of the rigid cervix tending to divert the blood propelled from the heart to the head, or whether it is a deviation of nerve force due to the former hindrance. If we look into the history of Mrs. P——'s case we will note that, from the fact of the functional periodicity being in an

[1] A paper read before the Brighton and Hove Medico-Chirurgical Society.

Digitized by Google

active condition during lactation, that this points to the high nervous tension of the ganglionic systems which is an essential factor in the reflex resultant which I am endeavouring to prove. Again, the fact of movements of the head causing almost coincident palpitation of the cardiac region points conclusively to the sympathetic influence at work in the whole excito-motor system. I am therefore of opinion that the eclampsia in the cases I have related was due to shock and not to diversion of blood or of nerve force. Now I have arrived at the following conclusions: given a very rigid cervix and a high tension of nerve force we may have convulsions occurring during labour, and that when these two factors are present it is possible to anticipate from sudden stretching of the unyielding parts conveying through a nervous system in such a state as I have mentioned a reflex influence on the brain proper causing shock and resulting in eclampsia. *En passant*, to strengthen my argument, I am wishful to refer to an analogy which, although very limited in degree, I consider applicable to the intention of the paper, and I therefore introduce it. I allude to sickness. Dr. Barnes places ovario-uterine vomiting under the category of convulsions. We are all of us well aware of the old nurses' proverb of a sick labour being a safe one, and we also know as a fact that it is usually coincident with the passage of the globe-head through the cervix, and therefore a safe one, because the convulsion explodes in the gastric organ. I had almost forgotten to draw attention to the two other cases, and refer these to the same category as Mrs. P——'s as to cause and effect, and I have said that the resultant is due to the reflex shock conveyed to the brain from the stretching of a rigid cervix either at will or by the head of the fœtus passing through it. And now I have arrived at a very important part of the subject—viz., the treatment of such cases as I have related. I shall consider it as an axiom that no practitioner should enter a lying-in room without chloroform. This is the sheet anchor in such emergencies as I have been discussing. And I go as far as to assert that its presence at hand is as essential, and probably more so, than ergot.

I have attempted to show that I have produced one form of eclampsia puerperalis by mechanical stretching of the cervix uteri without any poisoned state of blood. I shall consequently arrange my method of treatment under two heads: First, the preventive or forestalling; secondly, the immediate. I will commence with venesection, which I must discard as coming under either class, preventive or immediate. It may possibly be of service in relieving subsequently the comatose condition which in vascular temperaments arises from arrested circulation due to a relaxed reactionary condition of the vaso-motor system following the shock. But in two out of the three cases mentioned in this paper the system was anything but replete—in fact, the reverse—although the third case was not so hypernotic as to demand bleeding. Drawing your attention to my previous syllogism—viz., that given a rigid cervix and a certain explosive standard of the nervous system, I say there is every probability of eclampsia resulting, and on these grounds I think I may justify my belief in basing the *modus operandi* of treatment by using such means and administering remedies which are known to relax the tissues in question and reduce central nervous irritation. And amongst the preventive class I will take the following: belladonna, opium, bromide of potassium, chloral, and chloroform. Chloral has the combined effects of reducing the central nervous irritation as well as relaxing the tissues. Bromide of potassium acts more directly on the structure of the tissue of the cervix itself. When ordered as a preventive, I prefer giving the two drugs in combination. As to the immediate treatment when the paroxysm is going on, chloroform must be our sheet anchor. No recognised anæsthetic acts quicker, unless it be nitrite of amyl, the virtues of which I have no experience of. The former must be pushed to the surgical extent, and repeated as often as there is a recurrence of the eclampsia. After a time the patient remains in a more or less comatose condition, which may continue for some hours, or even days, without being fatal. The pulse and other general indications must be our guide as to whether we should use the lancet or not. We must use our discretion. I need not give any caution as to the necessity of avoiding all peripheral irritation, such as dashing cold water over the face, sinapisms, &c., which methods to check convulsions were rife in days gone by on account of their supposed restorative action, but which in enlightened scientific periods have been proved by the highest of obstetric authorities to act quite in the reverse manner. One word as to the forceps, and I am well aware of the fact of my trespassing on dangerous ground when I say I should forbid the use of them unless the head is pressing on the perineum free of the cervix, and then will be the time and not before when we should seek instrumental aid.

Brighton.

ABSTRACT OF PAPER ON

PERICHONDRITIS OF THE LARYNX.

BY F. DE HAVILLAND HALL, M.D., F.R.C.P.

AT the meeting of the British Medical Association in Leeds, after the reading of the above paper, the following points were submitted for discussion:—1. Is there such a disease as primary laryngeal perichondritis? 2. Are there any characteristics by which the laryngeal perichondritis of tuberculosis, of syphilis, and of cancer can be differentiated? 3. The occurrence of laryngeal perichondritis in enteric fever. 4. The causes of the dyspnœa. 5. The prognosis. 6. The treatment of laryngeal perichondritis.

Evidence in favour of the occurrence of primary laryngeal perichondritis was adduced, but the author laid stress on the difficulty of excluding the possibility of the perichondritis being of a secondary nature. In the diagnosis of the different forms of secondary perichondritis much difficulty was at times experienced. The presence of tubercle bacilli in the secretion from the larynx, pale and puffy swelling of the epiglottis and arytenoids, the occurrence of ulceration in the inter-arytenoid fold, and the existence of apical mischief in the lungs, spoke for the tubercular origin of the disease; the absence of pain, extension of ulceration from the pharynx, a history of past syphilitic manifestations, and the effect of full doses of potassium iodide were the chief points to be noted in syphilitic cases. In perichondritis of malignant origin, a thickened and infiltrated condition of the thyroid and cricoid cartilages and surrounding tissues, and the occurrence of hæmorrhage from the larynx, were the chief diagnostic points. Microscopic examination might be of use. The cause of the perichondritis of enteric fever was attributed to defective nutrition rather than to any specific inflammatory process. The absence of symptoms was stated to be a marked feature of typhoid perichondritis. Œdema of the larynx, immobility and median position of one or of both vocal cords, abscess, impaction of the necrosed cartilage in the glottis, collapse of the cartilaginous wall of the larynx, and, finally, in the more chronic cases, stenosis from cicatrisation, were mentioned as the causes of the dyspnœa in laryngeal perichondritis. The prognosis in this disease was always a gloomy one; in the primary and limited variety, however, it was more hopeful. Of secondary perichondritis, the traumatic and syphilitic varieties were the most hopeful, though, in the latter, stenosis, as the result of cicatrisation, usually occurred. In cancer the occurrence of perichondritis accelerated the end by exhaustion from the profuse suppuration. Typhoid perichondritis was a very grave complication.

Functional rest and the use of ice-bags, or Leiter's coil externally and ice internally, were enjoined for the treatment of the disease at the outset. Œdema should be treated by the application of cocaine and scarification, abscesses should be opened, and necrosed cartilage should be removed by the laryngeal forceps. Early tracheotomy was advocated, and subsequent dilatation by Schroetter's method practised. Allusion was made to the plan originally suggested by Dr. Duncan Gibb of splitting the thyroid and removing dead structures. This plan has been recently advocated by Dr. Sajous, and its employment in suitable cases was recommended.

OLD STUDENTS' DINNERS.—At the annual dinner to be held at St. Mary's Hospital Medical School, on Wednesday, Oct. 2nd, the chair will be taken by Dr. Broadbent, in place of Dr. Lees, who is unavoidably prevented from being present. — At St. Thomas's the annual old students' dinner will be held in the governors' hall of the hospital on Oct. 1st. Dr. Harley will preside.

CASE OF

CENTRAL RUPTURE OF THE PERINEUM, SCARLET FEVER, AND SEPTICÆMIA.

BY J. H. ASHTON, M.R.C.S.

AT about 1.30 P.M. on April 26th I was sent for to attend Mrs. W——, age twenty-three, in her confinement. I found her a well-developed woman, with regular but not very strong pains. On examining her, the os uteri was about the size of a shilling, the head presenting, and in the first position. At 2.30 P.M. the os uteri was fully dilated, and the membranes ruptured. At 4.15 P.M. the perineum began to distend; the pains were not very strong; the parts were moist, the pulse was quiet, and the head continued to advance gradually. A few minutes before the birth of the child, which occurred at 5.30 P.M., I observed the skin just in front of the anus cracking, evidently in consequence of its inability to dilate to a further extent; the crack extended with the next pain in a transverse direction, the skin in this situation being hardly thicker than a sheet of paper; at the same time the posterior commissure of the vulva began to tear. I immediately applied the forceps, but in spite of all precautions (in the way of support and direction of traction) the perineum was lacerated from the fourchette to the spot where it originally gave way. During the progress of the labour and afterwards the patient complained of sore-throat and thirst; the skin was cool and the pulse quiet. The following day (April 27th) the same symptoms were complained of. The perineal wound looked healthy; it had been left unstitched. Early on the 28th, fever with diarrhœa and constant sickness came on, the pulse was very rapid, and the throat was red, swollen, and painful. Superficial sloughing began on the right side of the wound, and extended over its whole surface; on the left side the same appearance presented itself, but to a less degree. On April 29th a copious red rash (scarlatinal) appeared, which spread over the whole body. At this time the external parts were swollen and inflamed with a profuse purulent discharge. Sickness, diarrhœa, and delirium had been present. On the following day (April 30th) the lochial discharge ceased. On May 5th the rash had entirely gone, and the wound assumed a healthy appearance. The treatment during the first part of the attack consisted in the administration of salines, with small quantities of stimulants; and during the latter part quinine in ten-grain doses was given, on the nights of the 5th, 6th, and 7th days, with tincture of digitalis and moderate quantities of stimulants; antiseptics were also applied locally. On the morning of May 14th the patient was seized with rigors, sickness, and diarrhœa, with rapid pulse and tenderness over the hypogastric region, the cause being evidently septicæmia, due probably to the discharge from the wound not having been washed away during the night. The tenderness over the hypogastric region passed away on the 17th, and the patient commenced to be convalescent on the 18th. No albumen was found in the urine drawn off by catheter.

Remarks.—Central rupture of the perineum has been known to occur in cases where the coccyx has been less curved forwards than usual, but the condition here was normal, and the cause of rupture evidently the large size of the child's head. It was apparent that rupture would take place some time before it actually occurred, also that the forceps would not only cause a rent, but probably a severe one—an opinion expressed and verified by the result. The sloughing appearance of the wound was due to the scarlatinal poison, which had manifested its presence prior to the outbreak of the febrile symptoms. The scarlet fever gave rise to neither peritonitis nor metritis, differing in this respect from the septicæmic attack where metritis occurred. In a collection of cases by Dr. B. Hicks[1] several of scarlet fever are recorded, in some of which local lesions were found, in others none. It is certain that scarlet fever in the lying-in state sometimes runs its course without any; and it may be inferred that, when present, they probably result from some local cause introduced from without, or arising within the patient's body, or from injury during labour. The infant did not take the disease, and this was the mother's first attack.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SUPPURATING OMENTAL CYST; ABDOMINAL SECTION; EXCISION OF CYST; RECOVERY.

BY JOHN WALDY, F.R.C.S. ENG.,
SURGEON TO THE SCORTON HOSPITAL.

B. H——, a girl eight years of age, was first seen in May, 1888, when she was suffering from pain in the lower part of the abdomen. Her mother stated that she had suffered at intervals during the last two years from attacks of abdominal pain, which had increased both in severity and frequency. The pain was not accompanied by vomiting, nor did it appear to be caused by food or induced by violent exercise.

On examination, the lower part of the abdomen was visibly enlarged, and measured twenty-four inches in circumference at the umbilicus. On palpation, a tense globular, hard, movable (in all directions) swelling could be felt. Over its surface a creaking feeling was perceptible during respiratory movements. It fluctuated in all directions, and appeared not to be deeply situated or to be fixed in the pelvis or lumbar regions. Percussion gave a dull note over the swelling, with distinct resonance all round. The hand could be passed below the swelling into the pelvis. A hypodermic needle withdrew pus.

My partner, Mr. J. H. Hutchinson, agreed with me that the tumour was either a suppurating hydatid or dermoid cyst, probably situated in the omentum, and that excision or drainage offered the only chance of cure. Accordingly we agreed to open the abdomen, and having obtained the assistance of Mr. Richard Bowes of Richmond, on June 6th I made an incision two inches and a half long in the middle line between the umbilicus and pubes. On exposing the cyst, it was found firmly adherent to the abdominal wall in front. These adhesions were separated, and after tapping the cyst, withdrawing half its contents, and clamping the opening with pressure forceps, it was found to be adherent to the intestines and liver. The child was now turned on to her right side, and a portion of the cyst having been drawn out of the wound, the cyst wall was freely incised and the pus completely evacuated. The second opening was again clamped, and the adhesions were separated without much difficulty until the descending colon was reached; here they were so dense and firm that in dissecting them off the bowel a small aperture was made, which was immediately closed by Lembert's suture. The cyst was now delivered, and the broad pedicle formed by the adherent omentum was divided between numerous catgut ligatures. The abdominal cavity was washed out with warm spring water that had been previously boiled, a drainage-tube was introduced into the pelvis, and the wound was closed in the usual way and dressed with iodoform wool.

On the following day the wool was saturated with red serous discharge. Pulse 130; temperature 100°; urine loaded with urates, passed without the aid of a catheter. Vomited two or three times. The drainage-tube was removed, and fresh wool applied. On the third day the pulse was 100; temperature 99°. Bowels acted naturally on the second day. On the fourth day the wound was healed, and the child gradually convalesced. The diet was warm water for the first twenty-four hours, milk-and-water for the following two days, then beef-tea and milk until the end of the first week, and afterwards a gradual return to ordinary food.

The clinical features of the case are interesting. The age of the patient suggested a dermoid cyst. The resonance all round the tumour, together with its free mobility and the fact that the hand could be passed between the tumour and the liver and spleen, and also below the tumour into the pelvis, as well as into both loins, excluded a tumour com-

Digitized by Google

mencing in any of the abdominal or pelvic organs. The cyst was unilocular and about the size of a large football; its walls were about an eighth of an inch thick, and to its lining three plates of bone were adherent. Microscopic examination of the fluid only demonstrated the presence of pus.

Catterick, Yorks.

ON THE USE OF PILOCARPINE IN THE FORM OF HYPODERMIC INJECTIONS IN THE TREATMENT OF DEAFNESS.

By ADOLF BRONNER, M.D.,
SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL.

IN the *British Medical Journal* of July 20th, Dr. T. Woodhouse reports on five cases of deafness which he treated with pilocarpine, according to the suggestion of Field and others. He is surprised to find that "no real good was effected." In four of the cases the patients were over sixty years of age, and had evidently been deaf for many years; and in one case the patient's age was forty-four, and deafness had existed for nine years. Dr. Woodhouse does not give us any particulars as to the exact nature and cause of the deafness. We surely cannot expect pilocarpine to cure all cases of deafness, irrespective of the nature and duration of the disease. How can we hope for any improvement in old chronic cases, in which there is perhaps much thickening and calcification of the membranæ tympani or fenestræ ovalis or rotundæ, or where the membrana tympani is absent or adherent, or there is much ankylosis of the ossicula, or where extensive changes have taken place in the internal ear or auditory nerve?

Pilocarpine can only be of use in certain classes of cases, and at present it ought to be our endeavour to define these classes as strictly as possible. In some acute or subacute cases we may reasonably hope not only to arrest the progress of the disease, but also in some cases to restore normal hearing; but in chronic cases we ought to be satisfied if we can prevent the deafness from progressing. In all cases in which the deafness is not entirely due to affections of the internal ear, we ought also to make use of the Eustachian catheter, in addition to the use of pilocarpine.

I have used pilocarpine in many cases of deafness, and in some with very good results. At present I have a girl of twelve under treatment who is suffering from a subacute affection of the middle and internal ear. After twenty injections of pilocarpine she can hear the watch with the right ear at twenty inches and with the left at six inches, and hear "whispers" (ninety-nine) at more than five metres with either ear. Before treatment she could not hear the watch at all, not even on contact, and loud speech (ninety-nine) at two metres. There is a history of congenital syphilis.

As far as my experience goes, the following classes of cases seem to be the most suitable for treatment by pilocarpine:—1. Deafness caused by acquired or inherited syphilis, due to changes either in the internal or middle ear. These seem to be the most successful cases. 2. Deafness due to hæmorrhage or exudation into the internal ear. 3. Cases of chronic catarrh, with recurrent exacerbations. 4. Cases of sclerosis or dry catarrh, but only in the initial stages. Normal hearing is very rarely restored in this class of cases, but one can frequently arrest the progress of the disease.

I will only add that I am still collecting cases and making further investigations in this very important subject, which I hope to publish *in extenso* at some future time.

Bradford.

POISONING BY STRYCHNINE; RECOVERY.

By ARTHUR E. LYSTER, M.R.C.S., L.S.A.

SOME time back I was called to a woman who had taken rat-poison. On my arrival (within fifteen minutes of the poison being taken) I found that the chemist who had supplied the poison had administered sixty grains of chloral. At once a full dose of sulphate of zinc and copious draughts of warm greasy water were given her, which soon produced free vomiting. Again more greasy water and sulphate of zinc were given, when again she freely emptied her stomach. About fifteen minutes after my arrival she developed tetanic convulsions, and at once chloroform was administered, and repeated constantly for at least an hour and a half. She recovered. The chemist who supplied the rat-poison told me it contained two grains and a half of strychnine.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

WEST LONDON HOSPITAL.

FIVE RECENT CASES ILLUSTRATIVE OF CEREBRAL SURGERY; REMARKS.

(Under the care of Mr. C. B. KEETLEY and Drs. DONALD HOOD, J. B. BALL, and COLMAN.)

(Concluded from page 595.)

THE cases which we have already published have been examples of (1) successful trephining for bullet wound of brain; (2) recovery after trephining for cerebral abscess; (3) exploratory trephining in a patient suffering from new growth of the pons, in which there was reason to suspect intracranial suppuration.

In Case 4 it is to be regretted that the operation was not performed earlier. The case was much clearer at first than at the time surgery was resorted to. There was then a most misleading set of symptoms superadded and masking the plain original indications—namely, a red and tender swelling above the left ear, a history of discharge from that ear given by one parent and denied by another, and some tenderness over the mastoid process. After a consultation it is not surprising therefore that the first trephining was performed with a view to exploring not only the motor part of the cortex, but also the temporo-sphenoidal lobe, well known to be the usual seat of abscesses connected with ear disease. The second trephining was done in the right place. It failed because it was a second trephining, and was therefore undertaken with less heart and thoroughness than the first. Had the exploration been as thorough and systematic at the second as at the first, the pus must have been reached. The second trephine hole was not exactly over the pus, because one does not trephine in the middle line directly over the superior longitudinal sinus. The fact that the symptoms, although cerebral and not spinal in character, were rather paraplegic than hemiplegic, at first pointed plainly to the situation of the pus, and, reading the case over again, it is plain that, with prompt action and a just faith in the doctrines of cerebral localisation, the collection of pus between the leg centre and the falx cerebri should have been found.

CASE 4. *Abscess (? tubercular) diffused between falx cerebri and left hemisphere, and also in left occipital lobe and on anterior and inferior aspects of left frontal lobe; trephining; death.*—Henry H——, aged thirteen, was admitted under the care of Dr. J. B. Ball, on Sept. 24th, 1888. His illness began on Sept. 11th with vomiting and headache. The former ceased after two days, but the latter continued. On Sept. 20th he was noticed to be "weak in the back and the legs," could scarcely walk, and the weakness was increasing. On the 23rd he was said to have been delirious at night, with twitching of the face and hands; bowels very constipated. Both personal and family history good; no injury; no tubercle; but a history of old ear disease and of discharge a week before the onset of symptoms.

Sept. 25th.—Restless, much pain in the head, frequently whistles and calls out, is slow at answering questions; skin hot and dry; pulse 72, regular. Pink flush on the face. There is a slight white fur over the tongue, and the papillæ are red and prominent. No paralysis of cranial nerves. Pupils dilated, normal. Slight right internal squint. Face twitches slightly (probably voluntarily). Arms and hands weak. Left leg weak; right leg can scarcely be moved; knee-jerks exaggerated; no ankle clonus. Abdomen supple, not retracted. No aural discharge. Temperature: evening, 102·4°.

Digitized by Google

26th.—Slight left ptosis (?) Rather duller; otherwise the same. Temperature: morning, 102·8°; evening, 102°. Pulse 88.

29th.—Temperature: morning, 100·6°; evening, 101°. Much pain down the back yesterday. Motions passed beneath him. Tongue protrudes to right. More noisy and restless.

30th.—Sensation in right leg seems much delayed. Knee-jerk less active than on right side. Plantar reflex scarcely perceptible. "A kind of risus sardonicus, with raising of upper lip"; left side slightly more than right. At 10 A.M. there was a rigor, and at 12 the temperature was 105°. Head shaved; mercurial ointment to be applied to it night and morning. Right eye: arteries tortuous, veins enlarged, disc hazy, but only a glimpse was obtained of it, owing to the boy's movements. The fundus of the left eye, as far as could be seen, was the same as the right, as regards vessels.

Oct. 3rd.—Yesterday both lower extremities were rigid with very excessive knee-jerks. Neck rather rigid and seemed to be slightly retracted. This morning the temperature dropped to 98·8°; pulse 92. Frequently calls out "mother," sleeps in intervals of calling out. Easily roused and answers simple questions correctly. Weakness of right arm doubtful. Slight but distinct drop of right side of face. The right leg can now be slightly raised. Knee-jerk excessive. Very slight rigidity. No plantar reflex. In the left no rigidity. Rectus clonus, but no ankle clonus. No plantar reflex. No retraction of head, ptosis, or squint. Abdominal reflex much less on the right side. Much wax removed from both ears yesterday. Right ear normal. In the left no sign of recent inflammation; (?) old perforation. Patient seemed much brighter in the afternoon, but very noisy at night. Temperature, 101°.

4th.—Temperature, 98·6°. Slight salivation. Gums a little swollen. A slight swelling, about two inches above the left ear, noticed last night, is now reddish and tender.

5th.—The notes show, if anything, a slight general improvement; but at 1.30 P.M. a rigor took place. Mr. Keetley saw the patient, and performed the following operation. After the head had been shaved, cleansed with liq. potassæ, soap, and nailbrush, the fissures of Rolando and Sylvius were carefully marked out on the left side of the head, and a semicircular flap was turned down, exposing the pericranium at the site of the tender swelling above the left ear. No evidence was observed that this swelling was connected with the cranium or its contents. The pericranium was therefore reflected and the skull trephined at the upper and anterior part of the wound—i.e., over the lower part of the motor area (about the situation of the facial centre). The button of bone was slipped through a small incision in the left thigh, and "pocketed," as it were, in the subcutaneous cellular tissue until wanted again. (Antiseptic precautions.) The dura mater bulged, but pulsation was well marked. On dividing it a little serum escaped, and the brain bulged strongly through the opening. The intracranial tension was unmistakable. An aspirator needle was pushed (1) straight in, (2) upwards into the leg centre, (3) horizontally into the hemisphere, (4) downwards through the temporo-sphenoidal lobe as far as the upper surface of the petrous part of the temporal bone, (5) backwards and downwards. A little frothy blood-stained fluid escaped, especially on the third puncturing. The dura mater was replaced as well as was possible. The brain bulged so as to make suture of the dura impossible. The piece of bone was taken from the thigh, and a sponge being held over it, it was clipped into small pieces directly over the wound by bone forceps. The flap was then replaced. Silver sutures; catgut drain. Dressing of wood-wool pads over iodoform gauze, the latter wet with sublimate lotion (1 in 2000). Fixed with gauze bandages and plenty of strapping.

6th and 7th.—Was certainly no better for the operation. On the 7th appeared aphasic, repeating a few words, such as "Mother," "Yes," "I want some water." Temperature 99° last night, normal this morning.

8th.—Passes motions unconsciously in bed. Temperature: evening, 101°.

9th.—Pupils for the first time noticed to be unequal (right larger than left). React normally; no squint. Facial paralysis marked. Tongue does not deviate to the right quite so much as yesterday. Temperature: morning, normal; evening, 102°.

10th.—Seems better. Recognises his mother. Understands a little better. Head a little retracted. Tongue protruded nearly straight. Leg and arm movements rather better. Has control over sphincters. Temperature 99·2° this morning; pulse 100, very much stronger. Marked optic neuritis in both eyes. Tortuosity of vessels much increased since last examination.

11th.—Dressed. A hernia cerebri apparently commencing at the seat of trephining. No pus, either superficially or on passing a probe into the posterior angle of the wound. It reached the trephine hole without resistance. Strands of catgut used for drain nearly absorbed, so the stump (externally) was removed. Iodoform gauze dressing. Face rather more drawn this morning. About 5 P.M. the patient became comatose. When restless he threw the left arm and leg about freely, but did not move the right limbs at all.

Second operation.—Believing that the symptoms pointed distinctly and principally to suppuration in the cortical centre for the movements of the right leg, Mr. Keetley trephined again, the portion of bone being this time removed from a point as nearly as possible just in front of the upper end of the fissure of Rolando. The dura mater bulged greatly, but there was pulsation. Two or three exploratory punctures with an aspirator needle were then made to a depth of an inch and a half, but unsuccessfully. The dura mater could not be stitched together. The button of bone was not replaced. Dressing &c. as in preceding operation. During the operation the patient did not change. His pulse was fairly good all through. Afterwards he lay as if dead, only just breathing with an almost imperceptible pulse. Some brandy was given, and patient revived. Temperature 99° at both 8 P.M. and 12 P.M.

12th.—A little stronger, but hardly conscious. Pupils equal. Tongue protruded nearly straight. Temperature 99° at 2 A.M., 100·2° at 6 A.M., 97·8° at 10 A.M., 98·6° at 2 P.M., gradually rising to 99·4° at 10 P.M. Afternoon and evening restless, rolling from side to side; "cephalic" cry.

14th.—Quieter. Right arm quite paralysed to-day. Leg weaker than before, but is still moved a little. Sensation seems impaired, not lost on right side. Squint more marked. Facial paralysis less. Pulse 125; good volume; rather low tension. Temperature 100·6° at 10 A.M.; 101° at 2 P.M. Incision of first operation healed excepting at the angles. Prominence and pulsation well marked. Second wound looks healthy, but a hernia protruded from the upper part of the incision, the size of a bean, when the dressing was first removed, but was a good deal larger before the new dressing was applied. A thoroughly cleansed probe was passed into the posterior angle of each incision. A small quantity of thick brownish fluid escaped from the first wound after the withdrawal of the probe. Temperature 99°. In the evening the patient was a little more intelligent. Puts out his tongue almost as soon as asked; it protrudes a little to the *left* now. Has taken in the twenty-four hours about six eggs and four pints of milk. Temperature 102·2° at 6 P.M.; 99·2° at 10 P.M.

15th.—Seems stronger, slept pretty well during early part of last night, but after 5 P.M became restless and cried a good deal. Rigidity commencing in right arm. Leg also slightly rigid, with rather less movement than before. Squint and facial paralysis about the same as before. Does not do as asked so readily; clutches at bedclothes; some twitching of face, especially about mouth; occasionally a slight tremor of whole body. This does not occur very often, and is very slight. Pulse 150, volume and tension fair; temperature, 10 A.M., 100·6°; 6 P.M., 102°; 10 P.M., 101·6°. Takes food well. Brandy (of which he had been taking three ounces daily since 8th) stopped.

16th.—Sinking. Some movement in right arm to-day; other parts as yesterday; clutches at his head and at the bedclothes a great deal. He died about 2 P.M. Temperature, 2 A.M., 102·2°; 6 A.M., 104·2; 2 P.M. (and after death), 105·6°.

Abstract from the notes of the post-mortem examination which was held three hours after death.—First wound showed a very small quantity of pus beneath the flap and emitted an offensive odour. Several of the replaced pieces of bone were adherent. The skull-cap having been removed the dura mater seemed healthy, and having been turned back pus escaped from the anterior surface of the frontal convolution, and very freely from between the two hemispheres as the falx cerebri was turned back, probably six drachms altogether, thick and offensive. At the inner aspect of the convolution joining the ascending parietal and frontal convolutions was a depression about the shape and size of a shallow teaspoon, evidently produced by a rather large collection of pus at

Digitized by Google

this point—i.e., the inner aspect of the centre for the right leg. The second trephine opening was about one inch external to this, or rather to the median line. The anterior two-thirds of the left side of the longitudinal fissure were covered with a pyogenic membrane of probably recent formation. From this backwards to the inner surface of the occipital lobe the pus was more fluid. At the postero-inferior angle of the occipital lobe was another small collection of pus under the dura mater, which had formed a small excavation in the brain substance. It was in connexion with the rest of the pus. The brain was otherwise healthy. No bone or ear disease was found, but the internal and middle ear were not examined. No tubercle was noticed in any part of the body.

CASE 5 (William P——, aged nine, admitted on the 19th of July, 1889) is added to show how easily a surgeon might be led into performing a premature and unnecessary operation. When first brought to the hospital (two or three hours after falling from a scaffold twenty-five feet high) his pupils reacted well to light and were natural in appearance, although he was unconscious. In three-quarters of an hour the patient was comatose, his pupils had ceased to react and were dilated, his right arm and leg were flaccid, had lost their reflexes, and there was slight right facial palsy. But when Mr. Keetley arrived at the hospital (which is four miles from the middle of London) coma and paralysis had given way to maniacal excitement, and instead of operation an enema of castor oil and the vigorous application of cold to the head, including the cold douche if necessary, were ordered. The cold douche was not necessary. The patient was conscious in a few hours. The next day he was merely irritable and confused; and on Aug. 1st (thirteenth day) he is described as "quite well; fairly intelligent." He is reported to have never been very bright and cannot read, although he has been to school.

NORTH RIDING INFIRMARY, MIDDLESBROUGH.

AN ISOLATED CASE OF FRIEDREICH'S DISEASE.

(Under the care of Mr. HINSHELWOOD.)

AN interesting case of Friedreich's disease has been under observation during the last nine months at the out-patient room of the North Riding Infirmary, and, as it presents several very interesting and unusual features, seems deserving of record. All the characteristic features of Friedreich's disease are present—the ataxy, the unsteadiness of the head, the affection of speech, the lateral nystagmus, the peculiar deformity of the feet, and the age of onset. The case presents a very complete clinical picture of the group of symptoms which Friedreich first described, and to which the names of Friedreich's disease and hereditary ataxy have been given. The most striking feature of Friedreich's disease is that it attacks many members of one generation, and scarcely any isolated cases have been recorded. This case is as yet an isolated one, and this gives it very special interest. Dr. Bury, in *Brain* (1886), says that up to that date only four isolated cases had been placed on record. It is possible that the rarity of such isolated cases is not so much due to the fact that they do not occur as that they are not recognised. Several cases of ataxy occurring in the same family at once suggests the diagnosis; but isolated cases are very apt to be overlooked, unless the examination be a very minute and searching one. It is possible, however, that this case may not remain an isolated one, as some other instances may yet occur in the same family, there being two members younger than the patient, one aged eight years and the other eleven years. As yet, however, it stands alone. Dr. David Drummond of Newcastle has recently seen the case, and agrees with Mr. Hinshelwood's diagnosis.

D. B——, aged twenty-four, is one of a family of five, of which four members are still alive—a brother aged eight, a brother aged eleven, the patient himself, and a sister aged twenty-six. The two brothers and the sister are in perfect health, and entirely free from any nervous symptoms. A younger brother died in early childhood from scarlet fever. There is no neurotic history in the family either on the maternal or the paternal side. The patient enjoyed good health until three years ago, when he first observed that he was unsteady on his legs. Since then his gait has gradually become worse, and the other symptoms have gradually manifested themselves. During the last twelve months all his symptoms have become rapidly worse. His present condition is as follows: He looks healthy and well nourished. His muscles are well developed, and there is no wasting. He cannot stand with his eyes closed, and his gait is markedly ataxic. He lifts his feet very high, and then brings them down with a peculiar stamp. During the last six months his gait has become very much worse, so that now he can scarcely walk without support. There is no impairment of power in the legs. The feet present the very peculiar appearances which have been frequently noted in Friedreich's disease; they are extended at the ankle-joint, so as to be in the position of talipes equinus. The instep is very highly arched, and there is extreme dorsal flexion of the great toes. The movements of the arms are slightly ataxic, and the grasp of both hands seems to be slightly weakened. The little finger of the right hand and the two adjacent fingers are often flexed into the palm, and he requires to straighten them out with his other hand. He carries his head bent forwards, with the chin resting on the sternum, and there is very marked antero-posterior curvature of the upper half of the spine. The head and neck are constantly oscillating with peculiar jerky movements in an antero-posterior direction, even when he is at rest, but these oscillations are greatly increased both in frequency and range when he attempts to walk. Sensations of pain, temperature, and muscular sense normal. Electro-sensibility and electro-contractility normal. The sensibility to touch is normal in the upper limbs and body, but impaired in the lower limbs, especially in the lower part of the legs and feet. He has occasionally slight shooting pains in the legs, and now and again attacks of headache. Both knee-jerks are completely absent. On the right side all the cutaneous reflexes are present and active, except the cremasteric, which is lost. On the left side only the abdominal reflex is present, but sluggish, and very faint. His speech is indistinct and jerky. During the last nine months it has become much worse. There is a peculiar slurring of syllables, and a tendency to run two into one; also occasional hesitation. There is slight twitching of the tongue. His pulse during the nine months he has been under observation has ranged between 120 and 140, never less than 120. His eyes, when fixed on an object, show intermittent attacks of lateral nystagmus. They give several oscillations, remain fixed for a time, and then oscillate again. The nystagmus is most marked on making lateral movements with the eyes either to right or left. The movement is then of a peculiar jerky character. Both bladder and bowels have become affected during the last twelve months. The bowels are very costive, and when he feels the desire he must relieve them at once. The sphincter ani offers little resistance to the passage of the finger. He can retain his urine for some time, but whenever the desire to urinate comes on, the bladder must be immediately emptied.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Linear Proctotomy.—Treatment of Intestinal Obstruction.

A MEETING of the Surgical Section was held on June 7th.

Dr. BALL defined the operation of linear proctotomy as the making an incision through the anus and rectum directly backwards to the coccyx and hollow of the sacrum; the following being the indications for its performance:—1. For the cure of non-malignant strictures of the rectum, in which gradual dilatation by means of bougies or other instruments is either impracticable or inefficient. 2. For the removal of growths situated high up in the bowel or in the hollow of the sacrum. 3. As a palliative measure instead of colotomy in advanced malignant disease. 4. As a preliminary step to amputation of the rectum. Dr. Ball brought forward two cases illustrating the first class:—Case 1: Male aged twenty-three years, five years' syphilitic history. Considerable ulceration of lower part of rectum, with tight stricture above. Bougies gave rise to great irritation, so linear proctotomy was performed. Relief to obstruction was immediate, and the ulceration healed without further difficulty. There has been no recurrence of the stricture (twenty months after operation), and the amount of incontinence is ex-

Digitized by Google

tremely slight. Case 2: Female, aged forty-seven years, for five years suffered from a morphœa-like condition, which produced puckered subcutaneous cicatrices over both breasts, heart, and abdomen. She also had some ascites. The vagina was contracted, the uterus fixed, and a tight smooth stricture of the rectum existed. This became so tight that her life was threatened from intestinal obstruction. The stricture, which would only admit about a No. 9 catheter, was divided, and all symptoms of obstruction obviated. Six months subsequently she developed stricture of the œsophagus, which proved fatal, no recurrence of the rectal trouble having taken place. The pathology of this case was doubtful, apparently not carcinoma; but as she died down in the country, no necropsy could be obtained. The following are examples of the removal of neoplasms by means of linear proctotom:—Case 3: Male, aged sixty-three years, rectum obstructed by soft tumour filling hollow of sacrum. An attempt to remove the mass by linear proctotomy was so far successful that the tumour, which proved to be a lympho-sarcoma, was completely extirpated; but, unfortunately, the patient died from septic peritonitis. Case 4: Male, aged twenty-six years, much worn down by the continuance of dysenteric-like discharge from rectum. A soft sessile growth could be felt at the highest limit accessible by digital examination, but, with the aid of linear proctotomy, it could be completely controlled. It was extremely vascular, and, in the patient's exhausted condition, destruction by Pacquelin cautery was deemed safer than extirpation. The patient recovered very perfectly, completely regaining his strength, and there has been, so far (eighteen months), no recurrence and no inconvenience from incontinence. Class 3: Dr. Ball did not consider that linear proctotomy could be favourably compared with colotomy for the relief of obstruction due to malignant disease. And in the fourth class, the consensus of surgical opinion was certainly in favour of adopting linear proctotomy as a preliminary to amputation of the rectum, and Dr. Ball had hitherto invariably practised it.—The PRESIDENT believed that the operation afforded a fair chance of curing non-malignant stricture of the rectum almost immediately.—Sir WILLIAM STOKES said it was new to him to hear that Verneuil advocated division by the knife instead of by the cautery, as he happened to be present at a discussion when that operator advocated the latter mode, but since then he seemed to have modified his views. Indeed, the tone of the discussion to which he referred was that the operation, whether done with the cautery or with the knife, was only temporary in its nature. He wished to ascertain whether Mr. Ball recommended, and, if so, what precautions to keep open the stricture, for in the justly popular operation of internal division in organic stricture of the urethra, unless precautions were taken to keep the urethra dilated the stricture returned.—Mr. BALL, in reply, said Verneuil's operation, as described in his paper, was first a division of the tissues by means of an écraseur, which was next inserted through a canula and then through an opening made with a cautery. He was not in the habit of using the knife. With regard to the subsequent treatment, in both cases of stricture a full-size bougie was passed for a certain time; but in one of the cases which he saw within the last week, the bougie had not been passed for over a year, and no difficulty whatever occurred in getting satisfactory relief from the bowels. Between stricture of the urethra and stricture of the rectum there was this difference, that the urine flowed through the same channel after the operation as well as before, while as the result of the operation for stricture of the rectum a new exit was made for the discharge from the bowel—namely, immediately below the tip of the coccyx, and therefore the probability of subsequent stricture was very slight.

Mr. W. THORNLEY STOKER read a paper on some points in the Treatment of Intestinal Obstruction. He dealt chiefly with the treatment of those cases where the obstruction was owing to the paralysed condition of the bowel due to the accumulation of fæces or flatus. In this class of cases a lumbar operation is rarely indicated, and, owing to the extreme meteorism, laparotomy is usually a very fatal proceeding. He urged the adoption of other measures previous to any precipitate opening of the abdomen, advocating the employment of pressure and massage, and the judicious use of purgatives. Of these latter remedies he considered undue fear existed. Of belladonna, when pressed to its full effect, he spoke highly, and quoted cases in evidence. Local treatment by rubefacients he stated his disapproval of, as he did also of opium, which he regarded as masking symptoms, and doing little or no good. Tapping the bowel with an aspirator needle or fine trochar he had found of great use where much tympanites existed. A large part of the paper was devoted to an attack on the "long tube," which he considers a dangerous and useless engine, productive of no effects which cannot be gained by the use of a shorter and safer instrument.—The PRESIDENT was of opinion, notwithstanding the strong outcry against opium, that that drug, if of use in any case of abdominal surgery, gave relief in intestinal obstruction. In his own practice he invariably used it subcutaneously. Inversion he had seen practised, but never with good results. The enema was of great use, not by O'Beirne's tube, but by the ordinary one. Puncture of the intestine also gave relief; but instead of the aspirator, he preferred using a trocar (one-tenth of an inch in diameter), and canula.

Reviews and Notices of Books.

Syphilis und Auge: nach eigenen Beobachtungen von Dr. ALEXANDER, Dirig. Arzt der Augenheilanstalt für den Regierungsbezirk Aachen. Pp. 234. Wiesbaden: Verlag von J. F. Bergmann. 1889.

IN this work Dr. Alexander places before us the results of twenty-three years' extensive practice, during which his attention has been specially directed to the effects of syphilis upon the eye and its surroundings. He possesses the records of 50,000 ophthalmic patients, and of these 1385 of very various nationalities were ascertained, with different degrees of certainty, to be suffering from the effects of venereal disease. He gives the records of several ophthalmic surgeons, who have treated 138,000 ophthalmic cases, of which 2998 were specific, or a percentage proportion of 2·16 cases. In his own practice there were 8 cases of disease of the lids and conjunctiva, 35 of the bones and lacrymal organs, 3 of the sclerotic, 146 of the extrinsic muscles, 59 of the intrinsic muscles, 75 of the cornea, 331 of the sweat tract, 107 of the retina, 568 of the optic nerve, 14 of the trigeminus and facial nerves, and 39 cases of congenital or hereditary disease. To each of these he devotes a chapter, introducing subdivisions under each head; the affection of the lids, for example, being considered under those of the integuments, the tarsus, and the conjunctiva. Hard chancre is rare. It has been seen in infants, owing to the filthy practice of some nurses of cleansing the eyelids of the infant with saliva, when themselves suffering from chancre. The prognosis is, Dr. Alexander thinks, not bad, healing taking place with a small scar only. We have, however, seen a case which terminated disastrously. In regard to the lacrymal apparatus, Forster ventured to state in Graefe and Sämisch's Handbuch that these parts invariably escape infection and disease of a syphilitic nature. Apart from other evidence, however, Dr. Alexander adduces a case of disease of the lacrymal gland which, from the attendant circumstances and the results of treatment, he had every reason to believe was of a syphilitic nature, and a similar case has been put on record by Albini. The affections of the cornea, which are regarded by Dr. Alexander under the head of syphilitic, are the interstitial form of inflammation and keratitis punctata, with and without iritis, as well as gummata. Interstitial keratitis he shows, by reference to cases recorded by different authors, is not always a sign of hereditary syphilis, but may proceed from direct infection; and he remarks very justly that, providing the iris and deeper structures of the eyes are not implicated, no matter how vascular and opaque the cornea may become, the prognosis is not unfavourable. Iritis of course occupies a long section, as it is so frequently due to this disease, the author estimating that nearly 50 per cent. of all cases of iritis are of syphilitic origin. It

Digitized by Google

occurs usually in the earlier stages in the first instance, and in one eye, the second eye becoming subsequently affected. He gives a very excellent description of the character of syphilitic iritis, which, however, unless gummata are formed, presents no very marked distinguishing features from ordinary iritis; such gummata occur in about 18 per cent. of all cases of iritis, and of course in a much higher proportion of syphilitic iritis. In regard to the retina, we have only space to give the conclusions at which Dr. Alexander has arrived, which are: That the retina is affected in syphilis in consequence of various forms of choroiditis syphilitica, constituting the several varieties of choroido-retinitis; that there may also be a simple retinitis, in which the disc and adjoining region of the retina is clouded, as described by Jacobson, the periphery remaining intact; that a form may occur in which there is exudation along the retinal vessels; that there may be retinitis with hæmorrhage in consequence of vascular disease and the formation of thrombi; and lastly, that there may be a central recurrent retinitis. Separate chapters are devoted to the hereditary manifestation of syphilis and to the treatment of syphilitic affections of the eye, and the rest of the work is taken up with an interesting description of the paralyses of the muscles of the eye, both internal and external, as indicative of syphilis. Altogether, the work is written in a very good style, the author nowhere seeking to obtrude his own opinions unduly on the reader, though founded on large experience, whilst he has read largely and profitably. We possess no similar work, and one of the junior members of the profession might with advantage translate the work.

OUR LIBRARY TABLE.

Commercial Organic Analysis. By ALFRED H. ALLEN, F.I.C., F.C.S., Past President of the Society of Public Analysts, Public Analyst for the West Riding of Yorkshire, &c. Second Edition, revised and enlarged. Vol. III. Part 1. 1889. J. & A. Churchill.—Mr. Allen has earned the thanks of all chemists and of all who are interested in chemistry for his valuable, clear, and accurate book. The new edition is greatly enlarged and improved, and has to a great extent the character of a new work. So much has been added and rewritten that the first edition is quite superseded. The title, indeed, is now almost too narrow, for so many methods of manufacture and so many details of physiological and general scientific interest are included that the book is to a great extent a manual of practical organic chemistry. The present volume opens with an account of some of the more important acids and allied bodies of the aromatic series. In this part we find an excellent account of the curious body which has become so celebrated under the name of "saccharin." The complex method by which it is prepared from the toluene of coal tar, and the tests—fortunately simple and satisfactory—by which it can be identified, are described in sufficient detail. It appears that—for the present, at any rate—its addition to beer is prohibited. A long and interesting section is devoted to the tannins, and the present state of our knowledge in regard to these important but troublesome compounds is well represented. No less than twenty pages are occupied by a description of the very numerous methods for the analysis of tannin matters which have been proposed. Here, as elsewhere, we are struck by the laborious research which the author has brought to bear on the subject, and the acute criticism with which he has interspersed the bibliography. But the most remarkable feature of the book is undoubtedly the long chapter—two-thirds of the whole volume—which deals with dyes and colouring matters. The chapter is almost entirely new, and, considering the enormous development of this branch of chemical industry in the last few years, we cannot wonder that Mr. Allen is dissatisfied with his work. He modestly asks in his preface for an indulgence, which will most readily be granted towards an attempt in which perfect success was impossible. But he has collected a great mass of material, descriptive and analytical, with care and skill; his classification is sensible and simple, and his chemical details, so far as we have tested them, are accurate. As an example of good scientific writing we may mention the sections on indigo and the final chapters on the recognition and examination of colouring matters and of dyed fabrics.

The Asclepiad. Vol. VI., No. 23. By BENJAMIN WARD RICHARDSON, M.D., F.R.S. Longmans, Green, and Co.—The memoir which Dr. Richardson has given to his readers in the present issue of his instructive and entertaining quarterly is that of Edward Jenner, accompanied by an excellent autotype portrait. The memoir of this "fortunate Esculapian," as the writer terms him, opens with a reference to the controversy that has been and is being waged about his name, and tells how at Berkeley itself the name does not kindle so much enthusiasm as that of Benjamin Jetsy, who "inoculated himself and his family with cow-pox many years before any medical man touched the subject." Dr. Richardson writes impartially enough to satisfy all but those who think they have proved Jenner to be an impostor, for he neither gives way to exuberant adulation on the one hand, nor to hypercritical contempt on the other. The appearance of this essay is timely, and it may be profitably read by the wide circle of those who take an interest in vaccination and its origin. Amongst the other papers in this number there is an interesting reproduction of one upon the Subclavian Arterial Murmur, written in 1861, and now republished with the addition of experience gained in the long interval, which, however, has not led the author to modify his conclusion that the bruit in question is largely produced by pressure. The papers on the Synthesis of Disease are continued, the action of organic acids and the induction of what is termed by Dr. Richardson "synthetic somnambulism" by the inhalation of the vapour of amylene being the subjects now dealt with. Among the Opuscula Practica there is a particularly instructive note upon the value of alcohol in certain cases shortly before commencing the administration of chloroform. Absolute alcohol, diluted with water (dose four drachms to one ounce and a half), is to be preferred to ether, brandy, or wine. In Ammonia as an Antiseptic we are reminded that our author thirty years ago read a paper on the subject at the Medical Society of London. The pages of the *Asclepiad* bear witness that the same love of inquiry and the scientific ardour evinced by the writer almost a generation since are still fresh, combined with a large measure of industry and literary skill.

American Resorts, with Notes upon their Climate. By BUSHROD W. JAMES, M.D. Intended for invalids and those who desire to preserve good health in a suitable climate. Pp. 285. Philadelphia and London: F. A. Davis. 1889.—The object of this work appears to be to bring to notice the great number and variety of health resorts in America, which should render it unnecessary for Americans to seek relief, as they now do in numbers, at the watering places of France and Italy. "If we, as a people, would more generally seek health in our own sanitaria, and our medical men would encourage their patients so to do, the value of these places of retreat for health would soon be appreciated and their fame become widespread." The book appears to be more intended for the general reader and the numerous health-seekers in search of information regarding climate than for members of the profession. It contains short sketchy notices of the principal health resorts under the heads of seaside, fresh-water, and mountain resorts, the mineral springs of the United States,

Digitized by Google

summer and winter resorts, and some very brief notes on mineral spas. From a professional point of view, the most important section of the work is the last chapter, occupying ninety-six pages, which consists of a translation of that portion of Dr. Woelkof's "Die Klimate der Erde" relating to North and South America and the Atlantic Ocean. There is also an excellent map of the United States, Canada, and Mexico. The book will probably prove useful in the direction intended by the author of bringing prominently before his countrymen the home resorts for invalids, but it does not contain much that would assist members of the profession in the selection of places to which it would be desirable to send invalids.

Algerian Hints for Tourists. By CHARLES E. FLOWER. Pp. 60. London: E. Stanford. 1889.—It would be difficult to give a more brief, clear, and correct description of this book than that of the author in his preface: "This is not an abridged guide-book; it is not a guide-book at all, but only an appendix to the guide-books. It gives no description of the places or objects to be visited, but only tells the reader what there is to see, and how to get to see it; further information it leaves to the guide-books properly so-called." It gives for Algeria exactly the information we have so often wished for but so seldom met with in our rambles both at home and abroad. We strongly recommend it to all who visit Algeria, either for a short tour or a winter's residence, feeling sure that it may save them time, temper, and expense.

Blackie's Modern Cyclopædia. (Con—Fir.)—We have received Vol. 3 of this work, which appears to be faithfully carrying out its purpose of providing a "Modern Cyclopædia of Universal Information and Handy Book of Reference on all subjects and for all readers." The first word treated in the present volume is "Cone," which is described in both its geometrical and botanical senses. The volume concludes with an account of Firdusi, the greatest epic poet of the Persians, and who produced an historical poem of 60,000 verses, containing the history of the Persian rulers up to 632 A.D. The illustrations and maps are, as usual, numerous and excellent.

New Inventions.

THE J.R.P. INSUFFLATOR.

WE have received from Messrs. Maw, Son, and Thompson an instrument designed by Mr. Philpots for use in the insufflation of suitable powders in various conditions of disease of the nose. It consists of three parts: (1) a mouth-piece, (2) a receptacle for the powder, to which is fixed (3) a flexible tube of rubber, at the end of which is attached a nozzle to be inserted in the nostril. The receptacle is composed of a chamber and a lid which screws into it; this is charged by filling the inverted lid of the box with the powder; the lid is then screwed upwards into the

body of the box, moderately tightly. When used, the lid is turned so as to bring niches on its edge in line with the tube. The nozzle is placed in the affected nostril, and a sharp puff given through the mouth-piece. When not in use, the lid is screwed tightly home, so that none of the powder can escape in the pocket. It is advised that the receptacle be refilled after the third or fourth application. It can be easily carried in the waistcoat pocket, and, if charged properly, used during the day. It is specially recommended by the inventor for use in cases of nasal catarrh or hay fever.

NEW ARTERY FORCEPS.

WE have received from Mr. E. Haines Cory a specimen of new artery forceps, which presents a novelty in the way in which it is kept closed after application to a wounded vessel. It is shaped at the end which catches the vessel much like those in ordinary use, the blades being serrated, and adapting themselves closely when apposed. The handles are so shaped that the one which may be called the lower extends with a slight curve, gradually becomes thinner, and forms a very elastic but strong spring, which meets the upper one—thicker, without spring, and altogether stronger in make—at the extremity of the half-S-shaped curve which it makes, and by a little pressure can be made to fasten on a side catch near its free end; the spring-like character of the lower blade enables it to remain on this ledge, while by its lever action it firmly closes the blades of the forceps. The whole is made of steel, and forms a light and rather elegant instrument. A little practice makes its manipulation easy; but its shape and smooth surface, without anything on which the fingers readily catch, is an objection to its employment when rapidity is of moment, and the instrument is rendered more difficult to hold in consequence of the blood from the wound both on it and the hands of the operator. It is easier to clean than the artery clamp forceps in common use, and takes up less room.

THE MAYBRICK CASE.

To the Editors of THE LANCET.

SIRS,—Mr. Bond is mistaken in attributing to me the suggestion that "some member of Mr. Maybrick's family or the nurses may have deposited the arsenic where it was found." I made no such insinuation; indeed, my thoughts pointed to another direction altogether, indicated in the evidence of the deceased's brother. I had as little sympathy as Mr. Bond with the Tichborne and Lipski hysterics; but those agitations were of a different character from the Maybrick controversy. I know nothing as to the innocence or guilt of the accused, but I do know that Mrs. Maybrick was found guilty "on suspicion." There was positively no evidence that she administered arsenic to her husband, and the Home Secretary distinctly states that the evidence did not "wholly exclude a reasonable doubt whether his death was in fact caused by the administration of arsenic."

In reply to Dr. Kirk, I may say that I overlooked nothing in my comparison between the Madeline Smith and Maybrick trials. The evidence on every point was very much stronger against Miss Smith than that against Mrs. Maybrick. But a study of the reports of these two famous trials will show the different treatment of the cases and of the evidence by the judge as well as by the jury. It is for the prosecution to prove the guilt of an accused, not for the accused to prove his or her innocence, which latter is often utterly impossible, even to the guiltless. It is ungenerous to contend that Mr. Matthews yielded to ignorant and unthinking clamour. After an exhaustive and impartial inquiry he remitted the capital sentence on grounds which will consistently involve the future liberation of the prisoner, an issue I have strong hope of yet witnessing.

I am, Sirs, your obedient servant,

London, Sept. 21st, 1889. NORMAN KERR.

THE REGENT'S CANAL.—At the last meeting of the St. Pancras Sanitary Committee the general insanitary condition of the Regent's Canal was considered. Dr. Smith said that, although the nuisance arising from the canal this summer had not been so great as in former years, owing to the spell of hot weather being of shorter duration, the bed of the canal was in a most insanitary condition, and it was a question whether they should not compel the Company to clean out the canal. Whenever a barge passed through, it stirred up the filth at the bottom. It was decided that the London County Council be requested to take action.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 28, 1889.

THE managers of the Metropolitan Asylums Board, at their meeting held on Saturday last, received a letter from the Local Government Board, directing attention to the increased powers which London possessed for dealing with cases of infectious disease. These powers are now very considerable. London has at length acquired compulsory notification of infectious disease, and although we have felt it our duty to protest against certain provisions in this Act, we none the less desire that it may accomplish its object and prove itself of service to the community. We are convinced that it will meet with no opposition from the profession, but, as law-abiding citizens, all will endeavour to carry out the duties imposed upon them. Some difficulties, however, may arise which are due to the construction of the Act. Medical men are expected to forward a certificate in respect of every case of infectious disease under their care to the medical officer of health of the district in which the patient resides. We fear the cases will be very numerous in which neither patient nor doctor will know in which parish the house is situated. Doubtless in some cases where the sufferer is but a lodger, the landlord will know to whom he pays the rates; but the landlord is not always himself resident, and under these circumstances, at the very least, delay must be occasioned. We believe the more efficient method would have been for these certificates to be sent to a central office, where within a few hours they could have been sorted and despatched to their proper destinations. We hold that the London County Council would have been a more proper recipient of these certificates than the Managers of the Metropolitan Asylums Board, for the information in the hands of the former would be used in detail, by the latter only in its aggregate, and statistical returns sent every week would have answered all possible requirements of the hospital-providing authority. As it is, the one central authority which, having the services of a medical officer of health, can watch over the health of London in respect of the whole area would have to wait a week before tidings of a widespread epidemic, such as occurred in 1866, would reach it. This perhaps is the weakest point in the whole Act.

The Managers have, however, under the Poor-law Act of 1889, obtained powers which will be much more useful to them than that of receiving notice of cases of infectious disease. They are now authorised by statute to receive into their hospitals any person who is not a pauper, and is reasonably believed to be suffering from fever, or small-pox, or diphtheria. The expenses incurred by the managers are to be paid by the guardians of the union from which the sufferer is received, and the guardians may recover the amount of these expenses as a simple contract debt from the patient, or those liable by law to maintain him, but any expenses not so recovered are to be repaid to the guardians out of the Metropolitan Common Poor Fund.

We do not doubt that eventually the guardians will not be at the trouble to obtain any repayment from the patient. It is so easy for them to be recouped from the common fund, it is often so difficult to recover money from a private individual, it is often so hard to distinguish between those who are paupers and those who are not; and further, it is so much to the interest of the guardians not to discourage the removal of the infectious sick to hospital, that we are convinced that in a little while the total expenses will fall upon the Common Poor Fund.

The Managers may under this Act also, with the consent of the Local Government Board, purchase land adjacent to their asylums; they may use their ambulances for the conveyance of the infectious sick to and from hospitals and places other than their own asylums, and thus the admirable service which they have created becomes available for the general use of London; and lastly, their institutions may be used for the purposes of medical instruction. The Act, therefore, in increasing the powers of the Managers, has conferred great benefits on London, and Mr. RITCHIE deserves the thanks of the metropolis for adding its provisions to the statute book.

THE study of epidemiology in its wider bearings has often direct and practical result. Faithfully pursued, there is much to be learnt from this survey of the distribution of infectious disease in various regions, since it is suggestive of some of the primal conditions that underlie the causes of epidemic outbreaks. The modern tendency to refer such diseases to a specific organised virus can, without difficulty, be harmonised with the older established facts upon the geographical distribution of disease, and the climatic and other conditions which seem to play sometimes so large a part in their production. Such at least is the inference to be gained from what is, perhaps, the most recent contribution to the subject—viz., an elaborate statistical survey of the prevalence of diphtheria and croup in Prussia during the eight years 1875 to 1882, by Drs. BRUHL and JAHR, of the Imperial Health Institute of Berlin.[1] By a most elaborate and painstaking comparison of the mortality from these affections in each of the several provinces of this extensive kingdom, these authors not only show how great are the variations in such mortality, but offer an apparently reasonable explanation for these differences, based on the prevailing meteorological conditions of the localities in question. It would be obviously impossible to follow them here through the maze of statistics upon which their conclusions are founded. It must suffice simply to advert to the more striking of their conclusions, which will doubtless be utilised by subsequent epidemiologists. The highest rates of mortality from diphtheria and croup are to be found in the eastern provinces of the kingdom; the lowest in the southern and western districts. It is shown that this mortality is on an average highest among infants of one to two years—which is contrary to the generally accepted belief. Further, it appears that in Berlin and the central provinces, as well as in the west and south, which contain the most thickly populated towns, there is a lesser mortality at this early age, or under one

[1] Diphtherie und Croup im Königreich Preussen, im den Jahren 1875-1882, von D. L. Bruhl und E. Jahr. Berlin: Hirschwald. 1889.

Digitized by Google

year of age, than in other districts. The mortality is next highest at the ages of from two to five years, and thence up to eighteen, after which it becomes comparatively low. The country yields a higher mortality than the towns; and the influence of the mortality from these causes upon the general death-rate is most marked between the ages of two to five years, for in some provinces these diseases account for nearly one-half of the whole mortality at this period of life. Such statements reveal the terrible extent to which diphtheria now prevails. It is thought to be a "modern" disease; but if this be so, it is no credit to "modern" inquiry and science that it has assumed such enormous proportions. Surely there must be a means for its subjugation yet to be found, since other infective diseases have been so markedly controlled in their extent by sanitation. The authors of this monograph do indeed indicate the lines on which diphtheria is to be met, derived from further facts which they have gleaned from their statistical studies. Thus they claim to have proved that the increase in mortality is closely allied with prevalent atmospheric conditions, the maximum mortality being in those parts of the kingdom where there is throughout the year less equability of temperature and humidity of the air. Where these two conditions are more equable, or where the air is warm and dry, there the mortality is lowest. It is remarkable, too, that the mortality from diarrhœa was higher in Prussia in those years in which the diphtherial death-rate was lowest; and that phthisis seems to prevail most in those provinces in which diphtheria occurs least, and conversely. It is shown that in Berlin the humidity of the atmosphere is greater in January than in July, and the difference in this respect between the air of a dwelling and the external atmosphere is correspondingly more marked in the ormer month, which is also characterised by a far higher mortality from diphtheria and croup (the difference being greater the younger the child), than in the latter month.

Hence the conclusion is made that a primary factor in the individual liability to the diphtheritic poison or in favouring its development is to be found in the change from an environment which allows of a relatively lessened exhalation of water to one which demands a greatly increased withdrawal of water from the respiratory tract. Such a condition is to be found in the difference in winter between the dry overheated air of dwelling-rooms and the external humid atmosphere; and in summer, the converse condition, if the rooms be not well ventilated. The inference is that far more attention should be paid to ventilation, even of the best houses, than is at present bestowed on them; and the authors comment especially in this respect upon the ventilation of sleeping apartments and schoolrooms. By a similar reasoning—which we regret to have to curtail so much—they commend the advice given by OERTEL to apply disinfectant sprays to the diphtheritic throat rather than more forcible local measures of treatment. They regard it of the first importance to maintain the mucous membrane in a thoroughly moistened condition, and consider that this is best attained by means of medicated steam inhalations which permit of being condensed on the lining of the throat. Thus, it is hoped, will the local conditions be less favourable for the growth of the diphtheritic organisms, and a greater opportunity given for the penetration of the mucous membrane by the germicidal agent.

THE value of resident appointments in our large hospitals is justly appreciated by the younger members of the profession. Gladly do they undertake the work, with all its inevitable discomforts and fatigue, and with full knowledge of the risks they incur in the discharge of their duty. They are expected to be at their post at all hours of day or night, ready to cope with all emergencies; and, independently of this, they have arduous duties in their wards, calling for the utmost devotion and self-sacrifice. Their rest may be disturbed by police cases, calling for the utmost caution to avoid errors of diagnosis or judgment, which would almost certainly be followed by all the vexation of a verdict with a rider which might damage the reputation of the institution as well as reflect upon the individual. They may be called up in the dead of night to deal with secondary hæmorrhage or other difficulties arising among the in-patients under their charge, and yet with all these distractions they have to preserve their steadiness of eye and hand to be ready to help in the operating-room, as well as to cultivate the *suaviter in modo* which is so emphatically demanded in all dealings with the sick and with their friends. These requirements are sufficiently onerous, and, we repeat, we believe they are fully realised and worthily fulfilled by the numerous band of young men, to whom so much responsibility is committed only after a long period of probation in ward work, and a careful estimation of their character by the hospital staff. The appointments are valuable, and they are valued. The opportunities for study and for the growth of experience are very rarely, if ever, neglected. It is in no spirit of lack of sympathy that, in view of charges of "hospital neglect" that are every now and then published in the lay press, we venture to address certain admonitory words to those who are so efficiently performing valuable work in alleviating distress and in securing the welfare of those committed to their charge. It is to be feared, however, that occasionally the *suaviter in modo* is somewhat overlooked—not intentionally, doubtless, but merely in the hurry and rush of their official work. Patients prove irritating with their appeals for admission, regardless of the assurance that all the beds are full. The difficulty of satisfying everybody when the necessities of the case require disappointment for many is obvious, still there is a way of conveying even the most unwelcome facts so that they seem perfectly gracious acts of concession. This relationship to the outside public, this task of selection and elimination, is precisely the point upon which, we fear, more attention and more tact are requisite. We are fully alive to the frequency with which wholly unsuitable cases are sent up—a frequency which almost forms a special class which might be termed "subscribers' cases," characterised more by an ardent desire to dispense charity than by a full appreciation of their suitability for treatment. Many cases are thus sent to hospitals, and by their triviality almost challenge brusque treatment; but, after all, the fault is merely the result of well-meaning ignorance of regulations or of an imperfect acquaintance with the true nature of the disease. In

Digitized by Google

rejecting such cases, signs of irritation in manner or in words are but too likely to alienate the good opinion of a valuable annual subscriber, as well as to cause disquieting general reflections upon the character of the individual. We repeat that we believe these errors of judgment to be quite exceptional; indeed, they may be, from one point of view, regarded as almost non-existent. It is highly probable that, the case once sent off with a few curt words, the whole incident is speedily lost sight of; it may merely be remembered for a few days as an absurd attempt to gain admission which was successfully repelled; but the mode, the manner, the tone—all these are forgotten, or rather they are remembered only by the friends of the patient, or by the charitable people who may come with him, and who bear away hasty and erroneous impressions of the treatment in hospitals, which they are not likely to keep to themselves. The possibility of thus unwittingly injuring the credit of their hospital during their short tenure of office might well be borne in mind by all who are thus brought into contact with the outside world. A hospital lives upon the good opinion of its friends and subscribers, which may be subverted by lack of care in dealing with people who are never truly patients of the hospital. All the wealth of kindliness and devotion should not be concentrated upon the sick in the wards; some of it should be dealt out to the far larger class who seek admission in vain.

A VERY important point in connexion with the isolation of infectious diseases is referred to in Dr. J. MACLINTOCK'S Annual Report on the Health of the Borough of Bradford. The Corporation have for some time past been desirous of erecting a separate hospital for small-pox; and, acting on the advice of the Royal Commission on Small-pox and Fever Hospitals, which advice has been emphasised by the occurrences which marked the Sheffield small-pox epidemic of 1887, it is explained that great care was taken in devising a method of dealing with the contaminated air of the wards so as to render it inactive in spreading the disease. The plans were then laid before the Local Government Board, who, it is stated, "declined to assume any responsibility in connexion with them, or to offer any suggestion calculated to assist." This attitude is one which it is certainly difficult to understand, and this the more since the Royal Commission which recommended the method of construction at which the Corporation of Bradford seem to have aimed was actually appointed at the instigation of the Local Government Board. And not only so, but amongst the subjects referred to them for report were: "The expediency of continuing the several existing small-pox.....hospitals.....; or, if it be considered desirable that they should be closed, the accommodation for small-pox.....cases which should be substituted"; and also, "The general conditions and limitations which should be observed in the case of the establishment of new hospitals whether by the managers, *or any other authority*, so as to insure, as far as practicable.....the protection of the public against contagion." It is true that primarily the work of the Commission related to the metropolis, but it can hardly be contended, in view of the words we have italicised, and of the results of the Sheffield epidemic, that the principles enunciated in the report hold good for one single large town to the exclusion of others.

The Bradford Corporation appear to have been altogether taken aback by the attitude assumed by the Central Authority, and it is stated that they pointed out that it was unreasonable to expect Bradford to undertake a costly experiment on behalf of the whole nation, and that since the department which constituted the head of the public sanitary service could not give local authorities the necessary information as to how they should proceed in this matter, it was their duty to find out a solution of the difficulty. The subject can hardly fail before long to be a pressing one; indeed, Dr. MACLINTOCK aptly remarks that the difficulty is not one for Bradford alone, since "other towns are beginning to feel the need of small-pox hospitals." It seems, therefore, clear that the Local Government Board, who in the past have rendered signal service to sanitary science by other investigations which they have made in the interests of public health, and for preventing the spread of infection, "ought to put themselves in such a position as to be able to advise sanitary authorities upon this important subject."

One other aspect of the question deserves notice. There is just a possibility that the Local Government Board have become so alive to the danger attaching to small-pox hospitals, and at the same time so convinced as to the efficacy, as a preventive of small-pox, of vaccination universally performed at infancy and repeated later on in life, after the manner laid down in the report of the German Vaccination Commission, that they have decided to take no further responsibility in the construction of small-pox hospitals, but intend to use the whole weight of their influence in the direction of the alternative means of prevention. But if this be so, it would be a distinct public advantage if their determination to that effect were made known as soon as practicable.

Annotations.

"Ne quid nimis."

THE ADMINISTRATION OF INFECTIOUS HOSPITALS.

SOME serious allegations have been made or implied against the sanitary administration of the Solihull rural isolation hospital on account of the occurrence of three cases of scarlatina in a row of cottages, to one of which a child had a week previously been returned as a convalescent from the sanitary authority's hospital. The allegations appear to have been based on an error as to the disinfection of the child's clothing, and had also in part to do with some question of partial desquamation about the child's foot. The story is altogether uninteresting, and we think that the imputations were in no way sustained; and this the more because ample opportunities for contracting scarlatina unfortunately exist at this time in and about Birmingham. But the occurrence is of importance as showing how essential it is for sanitary authorities so to organise and administer their infectious hospitals that they may be able to refute all allegations of this sort. For if the public are once led to believe that isolation hospitals fail to prevent the spread of disease, whether by reason of faulty administration, imperfect appliances, or otherwise, they will be

Digitized by Google

much less ready than they now are to assent to that form of isolation which is so necessary in the interests of public health.

THE WEST-END FEVER OUTBREAK.

ACCORDING to Dr. Corfield's last report, the cause of the outbreak of enteric fever at the West-end remains undiscovered—that is to say, its connexion with any special milk service cannot be definitely shown to have taken place. The difficulties inherent in such an inquiry in the metropolis are admittedly very great; and in connexion with this Dr. Corfield mentions that one firm of contractors, whose milk service was apparently included in the investigation he made, obtain their supply from about sixty different farms in different parts of the country. The bad smells which prevailed in several districts of London during, and subsequently to, the period of the outbreak call for the application of every possible remedy; but it is not at all probable that they were the cause of the somewhat sudden occurrence of enteric fever which simultaneously attacked a number of people in St. George's, Hanover-square, and other neighbouring London districts. In St. George's the outbreak only resulted in two deaths; but the whole story of the prevalence over the entire area affected has not yet been put together.

TECHNICAL EDUCATION.

IT is curious to notice how on every hand the demand for technical education is rising from advocates who have little or nothing in common except the formula which they all with one consent employ. On the one hand are those persons—ill advised persons, as we think—whose scheme resolves itself substantially into the substitution of the secondary school for the workshop as a place of instruction in the "mysteries" of the various forms of craftsmanship. In our own country they have not succeeded in producing much impression. The superiority of the workshop as a place of practical instruction is too pronounced to be overlooked. But in India we gather that they are more influential. At the National Indian Congress recently held at Allahabad a resolution on this subject was unanimously adopted, of which the drift and meaning was that India is not able to develop manufactures by the spontaneous operation of private enterprise, and that therefore it is the duty of the Government to open up an industrial future to its impoverished population by diffusing technical instruction in the industrial arts by means of technical schools. It may well be that in the case of a population like that of India, accustomed for centuries past to depend upon its Government for many things which more independent populations accomplish for themselves, it would be wise to apply principles different from those which would be applicable to our own case in the discussion of this question. But it seems impossible to suppose that technical instruction of this kind could possibly be given with any advantage in a State-supported school. Who would pay any attention to the instruction when no factory or other place where it could be turned to practical advantage existed within a hundred miles of the locality where the school existed? The cure for industrial inefficiency is to be found in the creation of factories, and not of schools, and factories can be better founded by private than by public enterprise. On the other hand, the advocates of a system of technical instruction which is to supplement, but not to supersede, the workshop have among ourselves secured a notable success in the passage of the Technical Instruction Act of the past session. It is quite true that this Act only empowers local authorities to act, and therefore it will not be automatic in its operation. But i will probably be set in motion here and there, and if it gets only slowly and gradually to work, so much the better. Corrections and improvements can be the more easily applied as its operation proceeds. The point of greatest importance, and one which it is a real and great gain to have made good, is that while the rate which the local authority is authorised to levy is to be expended in the teaching of the principles of science and art in their application to specific industries, it is not to be expended upon the actual teaching of the practice of any trade, industry, or employment. The distinction is all important. If the definition serves its purpose and is duly observed in practice, it will accomplish a great good both directly and indirectly. Directly because it will properly apportion between the school and the workshop those parts of a youth's education which they are respectively adapted to advance, and indirectly because it will open the eyes of the public to the importance of theoretical acquaintance with the principles of science on the part of the practitioners of any useful art.

THIRIAR ON VENTRO-FIXATION OF THE UTERUS.

DR. THIRIAR publishes in *La Clinique* an instructive clinical lecture delivered to his class at the Hôpital St. Jean, Brussels, on Ventro-fixation for Prolapsus Uteri. The term he proposes to use for the operation is "hysteropexy," from ὑστερον (the uterus) and πηξις (fixation). The condition of the patient, an elderly woman, who had been suffering from complete prolapsus for the last eight years, was such as to render all exploratory and operative procedures per vaginam difficult in the extreme, as she had ankylosis of the left hip, the thigh being fixed in an adducted position. There was a good deal of pain, and the uterus was visible on the outside of the vulva even when the patient was lying down. Pessaries had been tried, but were productive of no benefit. Under these circumstances it was determined to perform hysteropexy. The abdomen was opened in the linea alba between the symphysis and the umbilicus, and the uterus drawn forwards and fixed to the lips of the wound by three points of strong catgut suture, an iodoform dressing being subsequently applied, which was renewed in a week's time. Seventeen days from the time of operation the wound was healed, and the uterus could be felt high up and firmly fixed, so that the patient might be considered cured. She was, however, kept in bed for three weeks longer, when the uterus, being still firmly fixed, she was allowed to get up. Unfortunately, a fortnight later the prolapsus returned, but no pain or dragging was felt. The only thing to be done was to give her a cup pessary and to discharge her as incurable. In his remarks upon the case Dr. Thiriar points out that the operation is a new one, and a good deal more experience is needed to determine the best method of performing it. He does not think Caneva's plan of cutting down to the peritoneum and suturing the parietal and visceral layers of peritoneum together a particularly practical one, as it prevents exploration for adhesions and removal of uterine appendages if necessary. The plan adopted in this case was that of Leopold, except that catgut was substituted for silk, and no scraping of the epithelial layer of the peritoneum for the purpose of assisting the formation of adhesions was practised. The difficulty of fixing the uterus permanently to the abdominal wall is considerable. Müller of Berne, who amputates the uterus and sutures the stump to the lips of the abdominal wound, has found the adhesions break down and the prolapsus recur. Altogether Dr. Thiriar is not disposed to view hysteropexy with much favour—at all events when performed by itself,—though he thinks there may be cases where the prolapsus is accompanied by hypertrophic elongation of the cervix by rectocele or cystocele, where, as an adjunct to some other

Digitized by Google

operative measure, it may prove of value. He suggests that the chances of obtaining a permanent adhesion between the abdominal wall and the uterus would be increased by treating the uterus as Juffier treats the floating kidney—i.e., by peeling off the peritoneum from a considerable surface, which is then sutured to the abdominal wall. A lesson which this case teaches is not to be in too great a hurry to publish results. Had this case been published four or five weeks after the operation, hysteropexy would have been credited with a success which would have been entirely unwarranted.

MEDICAL FEES IN LIFE ASSURANCE.

A LETTER which we publish on another page gives expression to the annoyance and disappointment which are constantly arising to medical practitioners from the want of some well-understood practice on the part of the life assurance companies in the matter of their fees for the medical examination of proposed lives. In the case of a policy for a good round sum it is only natural that the companies should insist upon an exact and careful, even an elaborate, examination. In these cases there is rarely any difficulty. The office readily pays a fee of a guinea, or sometimes of two guineas, and the medical examiner furnishes a carefully prepared, detailed report. But it frequently happens that where the policy is to be effected for a small amount only, and the premium will not bear the cost of a guinea fee, a form is sent identical with the form used in the former case. The medical examiner is instructed to make an examination just as searching, and to furnish details just as minute, as for the largest risk that the company would be prepared to undertake, and only learns when his fee is sent down from London, perhaps, or Edinburgh, that the assurance is for a small amount, and that he accordingly is expected to accept half a guinea for his honorarium. This strikes us as being very unfair. It is not unreasonable that where the transaction is a small one the office should seek to economise in the matter of its medical fees, and there are abundant facilities for getting a medical examination made for half-a-guinea. The existing conditions of medical practice secure this advantage to the Life offices. But it is only fair that in such a case the company should be content with a report somewhat less painstaking than what they are accustomed to pay a guinea for, and that when the transaction is of this kind the medical man should be frankly told so at the first, that he may be under no misapprehension as to the terms of the contract under which he does the work required.

TRANSMISSION OF MICROBES TO THE FŒTUS.

THE question of the possibility of the direct transference of the virus of infective diseases from the maternal to the fœtal organism has, since the recognition of the apparent dependence of such diseases upon the presence of microbes, given rise to more than one series of experiments and some interesting clinical and pathological observations. Amongst the latter is a case recorded by Eberth (*Fortsch. d. Medizin*, 1889, No. 5), in which the possibility of such transmission of the typhoid bacillus was raised. It was the case of a young woman, who, in the third week of an attack of typhoid fever, aborted at the fifth month. The fœtus was expelled within its membranes intact, and macroscopically appeared normal; but in the blood, and in fluid expressed from the spleen and lungs of the fœtus, there were found typhoid bacilli (recognised microscopically and by cultivation), which also occurred in the intervillous spaces of the placenta. Drs. Eug. Fraenkel and F. Kiderlen (ibid., No. 17) record a very similar case, in which, however, the abortion (also at the fifth month), though occurring in the third week of an attack of typhoid, was associated with acute peritonitis, found to be due to an ovarian abscess and double salpingitis. The placenta, fœtal blood, and spleen were examined for typhoid bacilli, but with a negative result. On the other hand, cultures of staphylococcus pyogenes were obtained from the spleen. This case harmonised with some others where there was a similar absence of the typhoid organism in the fœtus; but it is pointed out that in all these cases the placenta was normal. It would seem (as in Eberth's case) that the placenta must be diseased for such transference of pathogenic organisms to take place, and the occurrence of hæmorrhage in the placenta appears to be a favourable condition for the transference. In this case, however, although typhoid bacilli were not transmitted, septic organisms were derived doubtless from the suppurating foci in the mother, and probably caused the death of the fœtus from septic infection. Fraenkel about two years ago injected subcutaneously cultures of the bacillus typhosus into three guinea-pigs. Two of them died in three days. They were both pregnant, and the fœtal part of the placenta was found to be hæmorrhagic. The placenta and the fœtuses yielded abundance of the microbes. There have been other and contradictory observations on this subject of the transmission of microbes from mother to fœtus; some asserting it to be usual, others that it requires special favouring conditions. Netter found pneumonococci derived from the mother in a seven-months fœtus; Tizzoni and Caltani found comma bacilli in the blood and serum of a five-months fœtus. The observations are, however, too scanty to permit as yet of the formulation of any definite notions on the subject.

IDIOT AND IMBECILE YOUTH IN GERMANY.

THE conference lately held at Brunswick on the best mode of treating these unfortunates was the sixth of the series, and, like its predecessors, evoked much interesting and reassuring fact. Dr. Sengelmann of Hamburg drew attention to the circumstance that in 1839 Germany had but one asylum for the idiot young; now she has forty-two such institutions, which up to date have had under care and treatment, mental and physical, 16,000 patients. The working staff of these asylums numbers 1200, under whose charge 2400 idiots are now undergoing instruction, while 1850 are being usefully employed, and 1700 are tended merely. Much having been done in their behalf, more yet remains to do—there being multitudes of idiots, particularly in the country, who are harboured in the workhouses, to their own misfortune and that of the other inmates. Germany, indeed, contains 50,000 idiots and imbeciles. For these latter a model institution exists at Brunswick, well worth a visit on the part of all among ourselves who are interested in this department of State medicine. One of its teaching staff, Dr. Kielhorn, led up to an interesting discussion by a paper on the "Imbecile Man in Public Life." He maintained: 1st, that the imbecile child requires a careful schooling, apart from the mentally sound child; 2nd, that the imbecile adult demands in public life special consideration and surveillance; 3rd, that the imbecile man is entitled, in the administration of justice, to exceptional indulgence; and 4th, that he is incapable of military service. As to the first of these positions, Dr. Kielhorn contended that for the effective schooling of the imbecile child its duration should be till the completion of the sixteenth year, the last two years (fourteen to sixteen) including tuition in a specially appointed testing or supplementary school, for which object the present number of such institutions should be adequately increased, with power to add the appliances and resources which educators of the imbecile find necessary. The conference finally resolved on the appointment of a committee to

Digitized by Google

consider the whole subject as evolved by Dr. Kielhorn, and to formulate the practical suggestions at which it arrived. This committee is to be composed of medical men, lawyers, schoolmasters, and clergymen, and its report will be read before the next conference, which is to meet in 1892 in Berlin.

THE MIASMATIC THEORY OF ACUTE RHEUMATISM.

To most practitioners acute rheumatism must appear essentially a personal or constitutional ailment, occurring most readily under certain unfavourable conditions, such as fatigue, exposure, depression, with wet or cold weather. There is a disposition, however, among some physicians to regard it as dependent essentially on miasmatic conditions. One of the latest expositions of this view is to be found in a paper read before the German Medical Society of New York by Dr. Leonard Weber, and contained in the *New York Medical Record* of Aug. 31st. Dr. Weber considers it nearly proved by the labours of Immermann, Edlefsen, Friedländer, and their pupils, that what he calls inflammatory rheumatism, and what is generally termed acute rheumatism, is not produced by taking cold—i.e., refrigeration of the heated surface of the body; but that it belongs to the class of miasmatic infectious diseases assuming an epidemic-like character at certain times, in so far as we are apt to see a larger number of cases when there is decreasing rain and moisture, while with an increase of the same the number of cases is diminished. Among other points he considers as nearly proved that rheumatism is also a house disease, the subsoil of houses in certain locations being infiltrated with the virus, which, after prolonged dryness, may be set free by the air currents carried into the apartments. In masked forms of rheumatism there may be an absence of one or other of the main symptoms and of the polyarthritis. Neuralgia of the trigeminal, sciatic, spinal accessory, or other nerves, with slight febrile movement, may be of a rheumatic nature, and yield to alkaline and salicylate treatment after other remedies have failed. Dr. Weber says that his records show that the greater number of his cases of polyarthritis rheumatica occurred in February and March, and again in the hot and dry summer months. We do not commit ourselves to the theory of the miasmatic or external origin of acute rheumatism. By the way, Dr. Weber does scant justice to our own countryman, Dr. Maclagan, who must be chiefly credited with this theory, which, indeed, led him to the use of salicin. We incline strongly to the personal and constitutional theory of its origin. But it is well to keep all well-argued theories in view. It is satisfactory to note that Dr. Weber regards the salicylate of soda, which he gives generally with the bicarbonate, as standing in the foremost rank of valuable drugs with which modern chemistry has presented us.

CASUALTIES AT SEA.

THE annual report upon casualties at sea contains a great body of extremely useful and interesting information on the subject with which it deals; but notwithstanding the copious statistics which it furnishes and the elaborate manner in which these statistics are tabulated, we are quite unable to collect from it what, if given, would be the most interesting information of all—namely, the extent to which life-saving appliances were brought into use and the efficiency which they exhibited under trial. The session which has recently closed has registered another disappointment to those who have been looking for some positive and practical outcome to the deliberations of the committee which have been considering this important question at the Board of Trade. So long ago as June last it was publicly stated that the committee had prepared their report; and if anything were wanted to rebuke delay in its production it would be furnished by the appearance in regular course of the long tale of fatalities which contributes the most painfully interesting chapter to Mr. Gray's somewhat dry record. Its production during the recess will not be nearly so effectual for good as its more timely production would have been while Parliament was in session, and although we ought, perhaps, to be grateful for such results as we do realise, it is not without some feeling of disappointment that we record the inability of the Board of Trade to take immediate or effective measures to enforce the adoption by shipowners of the best available means of affording to the passengers and crews whose lives are committed to their care the utmost security which life-protecting apparatus can secure. This is eminently a case in which the work of the department, to be truly effective, must be supported by a body of intelligent public opinion, and it is, therefore, much to be regretted that the sources of public information should not be more numerous than they are, and that, such as they are, they should not be made available to the fullest extent by well-timed publication.

DEATHS FROM HYDROPHOBIA.

A GIRL aged thirteen years died on the 20th inst., in St. Thomas's Hospital, from hydrophobia. She had been bitten in the lower lip two months ago by a strange terrier dog, by which also her father and brother were bitten. The dog was taken to the Dogs' Home, where it was destroyed. No post-mortem examination was held, but it was said not to suffer from rabies. For several days before the definite onset of the symptoms the child was melancholy and moping. On the evening of the 17th she had a catching in the breath when she attempted to drink, and was taken to the hospital at 2 A.M. on the following morning. She appeared wild, and looked suspiciously at everyone. She was able to swallow water, but with a slight choking feeling; at times, when water was offered, she had a kind of "sobbing catch" in her breath. She did not mind running water or cold air. The organs were apparently normal. At noon she could not swallow any liquid at all; even the sight of it caused a spasmodic contraction of the muscles of deglutition and respiration. There was much frontal headache. She was restless and unable to sleep. On the following day, the 19th, she was still more restless, and excited by the slightest sound. The spasmodic contraction of the pharyngeal and respiratory muscles came on every few minutes; they were induced by a touch, the sight of water, or a breath of cold air. The lips and tongue became brown, and the temperature rose to 100°. In the evening she was delirious at times, but rational when spoken to, and the difficulty in swallowing was less. On the 20th the convulsive fits were severe and frequent, the head flexed and fixed, the respiratory muscles and muscles of deglutition were fixed tonically for a few seconds, then clonically for about half a minute. The back was rigid, but without opisthotonos. She was very exhausted after the fits, and several times seemed on the point of suffocation. Morphia was given subcutaneously, also chloral hydrate by the rectum, and chloroform administered for twenty minutes before death, which occurred about 10 P.M. At the post-mortem examination the lungs were congested, but there was no other sign of disease.

Another death is reported as having occurred in the London Hospital. Last May, Mark Allen, aged fifty-seven, a painter, living at Henwood Side, Chigwell, was bitten by a retriever dog. He experienced no inconvenience until a few days ago, when symptoms of hydrophobia were observed. On the 23rd inst. he was taken to the London Hospital, evidently in the last stage of the terrible disease, and he died the next morning.

SIGNALMEN'S HOURS.

OF all occupations, none, perhaps, has been more vexed by the evil of overwork than that of railway service. In its different departments the same excess prevails. Guards, drivers, signalmen are in equal difficulty, and we need not therefore be surprised that a representative committee of the latter class in Birmingham have protested against a system which they feel to be oppressive, and which public opinion as a whole consistently disapproves. If some of the proposals contained in this protest appear to ask for a too radical change in the existing order of things, it must also be remembered that the abuses to be amended have been highly aggravated. According to the new arrangement six days will constitute a working week, eight hours a working day on main lines and in busy shunting yards, ten hours on branch lines and sidings, while pay will range from four to five shillings per day, except in the London district, for which a special tariff is to be fixed. A good deal might be said in favour of each of these projected changes. The first, however, has a somewhat Utopian aspect if we are to assume that it contemplates a cessation of Sunday labour in the signal-box. Such work as this is a constant necessity, and capable at best of reduction only. An eight hours' day is the desideratum of a great many, if not of all workmen. On some busy lines where traffic is nearly incessant, it would not be too short a period. As a rule, we should probably best adapt the exigencies of business to the worker's power of endurance by allowing nine hours as the normal term of service. In comparison with far longer periods of nearly continuous duty with which we have hitherto been only too familiar, it suggests a state almost of positive leisure. Whichever limit is finally agreed upon, it is most desirable that the present unsparing exaction of time and energy should come to an end. We must congratulate the Birmingham committee on their laudable desire to avoid an appeal to Parliament. Special Bills have their advantages, no doubt, but such matters as the regulation of labour are far better settled, if possible, by those concerned on a basis of common interests and necessities.

THE PROPHYLAXIS OF TUBERCULOSIS IN BAVARIA.

AT the instance of the Bavarian Home Office, the Ober-Medicinal Ausschuss (Superior Medical Committee), with Prof. Bollinger as its reporter, has just pronounced on the theory of Dr. Cornet of Berlin as to the spread of tuberculosis, and the best means of checking it. To Dr. Cornet's method and findings it has no exception to take, indicating as they do the danger proceeding from the pulverised sputum of the phthisical, a danger recognised by the profession ever since the discovery of the tubercle bacillus. What the committee objects to in Dr. Cornet's view is his entirely ignoring the influence of heredity and predisposition as factors in producing or inducing the disease. He goes so far as to stigmatise with the epithet "unselige" (fatal) the doctrine (practically and theoretically well founded) of an innate and inherited tendency to tuberculosis. The committee, in answer to the Home Minister's question, whether Dr. Cornet's results would warrant him in accepting these as the basis of practical measures for arresting the diffusion of the malady, remarks that Dr. Cornet's deduction involves an extremely optimistic standpoint, and that it cannot assent to his dictum that "the prophylaxis of tuberculosis attains its end with the simplest means imaginable." Measures of State for the prevention of the disease must await the solution of the problem whether in the genesis of tuberculosis contagious infection or inherited tendency plays the chief part. Dr. Bollinger, before an audience of the first Upper Bavarian Medical Diet recently proposed that the State prisons, in which the mortality from tuberculosis averages from 38 to 60 per cent., should be utilised for the experimental determination of the difficulty. With this view a prison should be repeatedly cleansed and disinfected as if it harboured plague or small-pox. Every case, moreover, of tuberculosis occurring in it should be isolated, or, better still, cleared out. The reduction, or disappearance in these circumstances of the tuberculous cases would prove that infection proceeding from the phthisical or from the infected locality played the chief part, and that inherited tendency was the less important factor. The committee concludes that the Home Office should institute the investigation thus recommended, and, considering the importance of the matter, should provide the necessary grant without delay. Meanwhile, our readers may be reminded that Dr. Cornet, with a dust suspected to be tuberculous, obtained by scrubbing a wall of from one to two square metres with a sterilised sponge, infected 392 porpoises, and that of these 196 shortly thereafter died under acute septic and purulent attacks, while the survivors remained partly unaffected, partly tuberculous—the latter dying in from thirty-eight to fifty days after infection. The whole subject, indeed, is agitating the profession in Bavaria to its depths, and the medical societies which meet during the second half of October have received from the Home Office a mandate to discuss the criticism passed by the Upper Medical Committee on the practical application of Dr. Cornet's views.

THE NEW PHARMACOPŒIA GERMANICA.

NEXT month the Reichs-Pharmacopöie Commission (Imperial Pharmacopœia Commission) meets in Berlin to frame a new (that is, the third) edition of the Pharmacopœia Germanica, so as to have the work completed for 1890. The scientific discoveries or inventions, and the practical experiences made known in materia medica since the publication of the second edition, will in this forthcoming one be incorporated, and rendered available. At the same time, it will not undertake, any more than its predecessors, to set forth all those remedial agents which individual German physicians have prescribed and apothecaries have made up. In the preparation of these remedies the most diverse rules and prescriptions have been followed, resulting in inconveniences and errors, sometimes serious to the public and compromising to the profession. To obviate or minimise this confusion, the German *Apotheker-Verein* (Society of Apothecaries) has resolved to issue a supplement (*Ergänzungsbuch*) to the forthcoming Pharmacopœia, which shall deal with all the remedies not given in the official dispensatories, and put the prescriber *au courant* with the latest and most accredited additions to his resources, both as to chemical quality and preparation. The profits accruing to the Society from the sale of this supplement will, it announces, be devoted to a philanthropic purpose.

FALSE TASTE IN DRESS.

As was to be expected, a paper lately read before the British Association by Mrs. Carmichael Stopes on "Errors in Women's Dress" was warmly received, and formed the starting point of an animated discussion. In this article the fallacies approved by women in regard to dress were divided into two classes: those which merely infringed the laws of art, convenience, or sense, and those which left their mark in permanent injury. The former division comprised a host of ungainly fashions and so-called improvers as crinolines, lengthy trains, tight sleeves, and the like, the latter such mischievous devices as the high heel and the tight corset. As a consequence of their use healthy exercise and even free movement were, said Mrs. Stopes, impossible, uncleanliness and infection clung to the trailing

Digitized by Google

skirts, walking on high heels became a mitigated hobble and strained the whole body, and grace, when enclosed in whalebone, a synonym of perverted development and consequent ill-health in which posterity claimed a share. In the discussion which followed, the practice of tight lacing received a principal share of attention. There were several avowed champions of the corset, evidently more or less under the impression that the dangers of tight lacing had been exaggerated. The balance of medical opinion of course supported an opposite view, and this was fortified by the president's experience of injury done to the viscera, and actually traceable to persistence in this disfiguring custom. Such questions as this are not of a kind to be settled in the course of a few academic discussions. The clue to their true method of solution was suggested by the lecturer when she referred to a pernicious dress custom as a falsification of truth. It is the dislike to simplicity, the hankering after showy, though false, ideals, which are mainly accountable for the patience of women under the deforming yoke of fashion. Their emancipation, therefore, cannot be the work of a day. It will not be brought about by the warnings of experience alone. The process of training must go deeper, and act on taste by affecting the moral sense on which it is moulded.

UTERINE TUBERCULOSIS.

AN interesting case of primary tubercular disease of the Fallopian tubes has occurred in Professor Lebedeff's wards. The patient, who was the widow of a man who had died of phthisis, was of a cachectic appearance and suffered from amenorrhœa. On examination, a firm, nodulated, intra-abdominal tumour was made out, situate in the space of Douglas. An attempt was made to remove the tumour, but had to be given up as disseminated miliary tubercle was found affecting the peritoneum. The intestines and the uterine appendages too were all matted together. Six weeks after the attempted operation the patient died with symptoms of general tuberculosis. At the post-mortem examination miliary tuberculosis was found affecting the peritoneum, the lungs, the pleuræ, the colon, and the mucous membrane of the uterus. Both the Fallopian tubes were dilated and filled with pus, the epithelium in parts being absent. The intensity of the destructive process was greatest in the tubes, and became less marked towards the periphery. In sections, tubercle bacilli were found; there was no tuberculosis, however, in the ovaries, and only the mucous membrane of the uterus was affected.

THE SUFFOLK GENERAL HOSPITAL.

WE much regret to learn that the affairs of the Suffolk General Hospital at Bury St. Edmunds have again assumed a critical phase; and the three members of the medical staff have once more sent in their resignations. It may be recalled that about six months ago a proposition to increase the staff did not meet with the approval of the present members, who saw no necessity for it; and that after two animated meetings it was decided to postpone the question for twelve months. Some of the governors do not seem to have been satisfied with this, and on the 17th inst. a meeting was held on the requisition of five governors to consider the bye-laws which dealt especially with the medical staff in its relation to the government of the hospital and also with the constitution of the staff. The medical men absented themselves from the meeting, but sent a firm protest against the proposals, which, if carried, would have involved a decided subordination of the medical to the lay government. Their supporters at the meeting, too, were in a minority, and retired after failing in their endeavour to urge a more reasonable course upon the meeting. The remainder of those present, some twenty in all, proceeded to pass resolutions amending the bye-laws, and recommending the appointment of a fourth medical officer. Under these circumstances there could be no other course open to Dr. Image, Dr. McNab, and Mr. Kilner than to send in their resignations. The institution will suffer a severe blow from this singular lack of consideration for its honorary officers, and there is likely to be much further difficulty in store for it, especially when it comes to the question of filling up the vacant appointments.

ANTISEPTIC ACTION OF CHLOROFORM AND OTHER VAPOURS.

DR. SEGALL has published in the *Münchener Medicinische Wochenschrift* an account of some observations in which he has been engaged with the object of determining the amount of antiseptic action possessed by the vapour of chloroform, of formaldehyd, and of creolin. The method employed was to infect the jelly (previously liquefied) in a test-tube with the particular microbe under investigation. After the infected jelly had been allowed to solidify, a small tube containing chloroform, creolin, or a 10 per cent. solution of formaldehyd was suspended over it, so that the surface of the jelly should be exposed to the action of the vapour given off, the mouth of the test-tube being closed with a well-fitting plug of cotton wool. The greatest effect was produced by the vapour of chloroform, this being found to have a nearly equal effect on all the different bacteria experimented on, these including staphylococcus pyogenes aureus, bacillus prodigiosus, and the bacilli of pneumonia, of typhoid, of anthrax, of cholera, &c. The upper part of the jelly remained clear and free from microbes, while the deeper layers presented evidences of the existence of numbers of colonies. In the tubes containing formaldehyd, though only in a 10 per cent. solution, there was also a great difference between the superficial and deep layers; while when creolin was employed this difference was much less marked, though the antiseptic action was greater than that of the fumes of carbolic acid, which have been shown to exert no preventive action on jelly cultures of the cholera microbe.

COCAINE POISONING.

DR. VINOGRADOFF gives, in the *Ejenedélnaya Klinicheskaya Gazeta*, an account of the post-mortem examination in a well-known remarkable case of cocaine poisoning, where a young woman who was suffering from a tuberculous rectal fistula was given twenty-two grains of cocaine by means of repeated rectal injections in order to produce local anæsthesia for an operation which consisted in scraping the anterior wall of the rectum with a sharp spoon. In a quarter of an hour the patient became excited, and began to suffer from clonic spasms in the limbs, opisthotonos, and cyanosis. Death occurred from asphyxia, in spite of tracheotomy and prolonged performance of artificial respiration. At the post-mortem examination the blood was found to be fluid, and of a dark brown colour, as in cases of poisoning with chlorate of potash. There were hyperæmia of the brain and of the lungs, exudative glomerulo-nephritis, evidently of long standing, together with ulceration of the colon and rectum, reaching down to the submucous tissue. Microscopically, there was found albuminoid degeneration of the nerve cells, of the cerebrum, of the heart muscle, of the liver cells, and of the epithelium of the urinary tubules. Dr. Vinogradoff compares this with three other published cases of death from cocaine poisoning, and with cases in which large doses had been given with and without the occurrence of toxic symptoms, and shows that as much as forty-five grains have been borne without any ill effects.

Digitized by Google

The fatal result in the foregoing case—which, it may be remembered, led to the suicide of the distinguished surgeon who operated—is to be ascribed to the increased power of absorption of the ulcerated intestinal wall, and to the retardation of the kidney secretion by the diseased condition of the glomeruli. It would therefore appear that when there is any question of giving large doses of cocaine a careful examination should be made of the condition of the kidneys, and if there is any ground for supposing them to be diseased or functionally inactive the greatest caution should be employed. It may be remembered that before operating the unfortunate surgeon asked one of his colleagues, who was a professor of therapeutics, what dose of cocaine might safely be given, the answer being, "Not more than two grains." So that the greatest diversity of opinion exists regarding the maximum dose of the drug.

SECONDARY EFFECTS OF PARENCHYMATOUS INJECTIONS AND EXPERIMENTAL PUNCTURE.

DR. DECKER reports to the *Münchener Medicinische Wochenschrift* the following two interesting cases from his clinic in Würzburg. A strong girl of twenty years of age, who had borne six previous parenchymatous injections of mercury well, presented after another injection of one-third of a grain of carbolate of mercury into the nates marked symptoms of collapse—that is to say, dyspnœa, marked cyanosis, œdema of the eyelids, small pulse, and vomiting. The same symptoms of collapse appeared in another female patient after an experimental puncture in the hepatic region, and the author believes that the same cause led in both cases to the same result—namely, traumatic excitement and consequent paralysis of the vasomotor nerves, leading to marked abdominal plethora, cerebral anæmia, irregular action of the heart, and venous congestion.

ASYLUM MANAGEMENT IN NEW ZEALAND.

A BLANK petition for presentation to the Honourable the Legislative Council of New Zealand has been sent to us which embodies many points which it is desirable should be secured in the management of asylums either for inebriates or the insane. Amongst others, the petitioners pray that medical officers should not be appointed to such institutions without having had special experience or training in this branch of medicine. The only question about such a petition is whether the prayers of it are not so obvious as to be superfluous.

TYPHOID FEVER IN BUDA PESTH.

THE text of a report of the medical officer to the city of Buda Pesth, Dr. Gebhardt, upon the prevalence of typhoid fever there, appears in the *Allg. Wiener Med. Zeitung*, Nos. 37 and 38. It appears that since August, 1888, the number of cases of this fever had risen remarkably, with the exception of April and May of the present year, reaching to as many as 647 in August, 1889, as against 337 in July and 104 in June. The total number of cases for the whole of 1888 was 1667, the deaths being 150, giving a mortality of nearly 9 per cent.; whilst during the next seven months and a half (to Aug. 15th) the cases amounted to 1404, deaths 190, or a mortality of 13·6 per cent. Dr. Gebhardt lays stress in his report upon the diffusion of the disease by means of drinking water, and calls attention to the defective sanitation of the city in respect to drainage and water supply. He closes his report by asserting that until the inhabitants will drink filtered water, and the drainage and dwellings in the city be improved, no diminution in infectious disease can be expected.

THE SOCIETY OF GERMAN PHYSICIANS AND NATURALISTS.

IN the sixty-second Congress of this Society, which, last week, concluded its sittings at Heidelberg, natural history preponderated over medicine, while both had in great measure to give place to discussions bearing on the organisation and standing rules of the Society. These, as of local, rather than of international, interest, need not be noticed further than to remark that they will immensely enhance the efficiency and authority of a Society which, as its President, Professor Quincke, showed in his opening address, had more than quadrupled its membership since its origin in 1827, and had increased its sections for special discussions from six to thirty-two! Of purely medical interest were the proceedings in the section for "Climatology and the Hygiene of the Tropics," in which that quarter of the globe as a residence for Europeans was the theme of learned and animated discussion—the question of "Malaria," its nature and origin, its prophylaxis and cure, receiving particular attention. Professor Minkowski of Strasburg enlivened the section for home-medicine (*innere Medicin*) with a report of his investigations on "Diabetes Mellitus, as a Consequence of Extirpation of the Pancreas." His deduction from these, that this grave malady must be referred to impairment of function in that viscus, was keenly debated and obtained provisional acceptance from some of the participants in the discussion.

PATHOLOGY OF SEVERE BURNS

DR. OSCAR SILBERMANN of Breslau, studying the clinical and pathological signs of the destruction of numerous red-blood corpuscles, found by his experiments: 1. That after extensive burns of the skin the red blood-corpuscles alter their form and lose their power of resistance to heat, drying, compression, and staining. 2. In consequence of these alterations numerous thromboses in the arterioles and capillaries, especially in the finer branches of the pulmonary artery, occur, leading to stasis in different organs—e.g., lungs, kidneys, stomach, bowels, liver, spleen, skin, and brain. 3. The large deviation of the pulmonary capillary circulation produces a considerable impediment to the emptying of the right heart and serious venous congestion, as well as dangerous arterial anæmia. 4. This state, coupled with the above-mentioned symptoms, leads to bleeding and parenchymatous alterations in the affected organs. 5. The interference with the circulation also produces dyspnœa, a small pulse, angina, eclampsia, and anuria, as well as a remarkably low temperature.

HEALTH AND SPIRITS.

WHATEVER may be thought to the contrary, the standard of health is as liable to fluctuations as the weather. The barometer is, in a measure, the gauge of the state of the weather, but we have no instrument for estimating even with an approach to the truth the state of the vitality of any individual. The customary salutation, even when replied to in the usual adverbial manner, is certainly no accurate criterion of the state of the health, since a general paralytic often *feels* much better than he has any physiological right to do. And, in opposite fashion, a man who does not know how he feels may be in first-rate health, or at least in a splendid condition for opposing those forces which are constantly tending, like the force of gravity, to bring a man to earth. Everyone knows, in greater or less degree, that which makes for his physical welfare, but it is not always realised to the fullest extent that an improvement in the *feeling* of health is by no means always desirable in the interests of longevity. To feel extraordinarily well costs

Digitized by Google

much, and the excessive expenditure of mental force may derange a considerable number of corporeal functions. The desire to want to be in good "form" requires restriction in the case of many nervous individuals, whose powers are not always equal to their appetite for high spirits.

TUBERCULOUS MILK.

AT the first general meeting of the South Durham and North Yorkshire Veterinary Medical Association, held at Darlington on the 18th inst., an address was delivered by the President, Mr. Nettleton of Northallerton. In the course of his remarks he referred to the transmission of diseases from animals to man, and especially dealt with the subject of tuberculosis, which he said was a source of contamination of milk; and he remarked that the number of diseased cows in England at the present time was enormous, and yet as long as they could walk and the mammary glands secrete the milk was used for human consumption. It had been demonstrated that calves dying from acute diarrhœa when a few months old, having been born of healthy parents but suckled by a tuberculous cow, owed their death to tuberculosis. He believed there would be less human phthisis were measures taken to stamp out the disease. Another feature, he pointed out, is that the cream is always richer in the milk from a tuberculous cow—a "richness" which, he suggested, might be due to the admixture of pus with the secretion. (!) The disease is more common in Alderneys and Guernseys; he had never met with it among black cattle.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.

THIS well-known society shows by its last annual report that it fully maintains the reputation it has acquired for useful sanitary and philanthropic work. Amongst the matters dealt with during the past year were questions relating to the Manchester bye-laws, the control of infectious diseases, especially in relation to school attendances, the closure of the Ardwick cemetery, the insurance of infant lives, cheap baths, &c.; and the Association also made representations to the Government to urge that medical officers of health should be dismissible by the central authority only. Conferences relating to the high death-rate of certain parts of the city of Manchester, and health lectures for the people, were also held. One special feature of the association is the valuable help it secures from educated ladies in connexion with visits to the homes of the poor, the provision of cheap meals for children, and the children's holiday fund. The association also carries out its valuable labours in such a way as to secure the hearty co-operation of the medical officers of health of the districts with which it deals.

OPHTHALMIA IN THE STRAND SCHOOLS.

A DISCUSSION arose at the Strand Union meeting last Tuesday on the reading of the report of the medical officer in charge of these schools. One member of the board, Mr. Prescott, moved that the children afflicted with ophthalmia be bathed separately from the other children. He said there were 166 cases of ophthalmia at the schools out of a total of 330 children, and that was a terrible state of affairs. Only nine of the sufferers were in the hospital, the remaining 157 being in the body of the schools with the healthy children. The guardians had a great responsibility in the matter, it being a well-known fact that ophthalmia frequently ended in total blindness. Mr. Dart, in opposing the motion, said he thought it was great assurance for anyone to interfere with the doctor at the schools. The motion was then put and lost. We may, perhaps, have occasion to refer to this subject again.

TORTICOLLIS IN INFLAMMATION OF THE MIDDLE EAR.

TORTICOLLIS, when it occurs in the course of acute otitis media, has generally been looked upon as a very serious complication due to periostitis of the mastoid process, and the formation of an abscess, with myositis of the sterno-mastoid. That this is not always the explanation of the complication is shown by Dr. Radsikh in an article in the *Meditsinskoë Obozrênië*, in which he gives an account of a case of inflammation of the middle ear following measles, which on the third day became complicated by torticollis, this being due to periadenitis of the neck, and Dr. Radsikh suggests that in these cases enlarged and inflamed glands in the neck may frequently be the cause of wry neck.

FEVER IN LONDON.

THE number of cases of fever in the hospitals of the Asylums Board was 1320 at the end of last week, as against 1000 a month before. During this period, 649 fresh cases have been admitted and 240 have been discharged as recovered. Of the cases under treatment, 1123 were cases of scarlet fever, 108 of diphtheria, 80 of enteric, and 2 of typhus. The appearance of typhus at this period of the year would in past times have led to the fear that the disease would attain unusual prevalence; it is, however, so long since this disease was practically banished from our midst that, without exceptional distress and an exceptionally cold winter, there is no reason for thinking that there will be any prevalence of this fatal malady. One of the cases occurred at Battersea, and may perhaps be related to the return of hop-pickers. Again no case of small-pox is known to have occurred during the month.

HYDROCEPHALUS.

DR. RODIONOFF mentions in the *Meditsinskoë Obozrênië* a somewhat remarkable case of recovery from chronic hydrocephalus in a child of eleven months old. The mother took good care of it until it was two years old, and then left it to itself. It was thus exposed to a hot sun for many weeks, and, strange to say, a year later the size of the head had diminished, and the child was able to creep about. When it was four years old the hydrocephalus had disappeared, and the child was able to talk. Dr. Rodionoff seems disposed to refer the cure to the action of the sun's rays.

TUBERCULOSIS IN SLEEPING CARS.

DR. WHITTAKER of Cincinnati has lately (*Nashville Journal of Medicine and Surgery*) drawn attention to the palace car as a medium for the dissemination of tuberculous disease. He says that the cars, owing to the caprice of individual travellers, are generally ill-ventilated, and there is no regard paid to the liability of infection through the sputum. The point is the same as that raised lately by a traveller in the *Australian Medical Gazette* with respect to ships' cabins; but, as Dr. Whittaker says, in some of the express trains a passenger may be literally confined in an atmosphere containing tuberculous dust for days together. He urges the replacement of plush by leather, of carpets by rugs, of curtains by wooden or leather screens, and *inter alia* the provision of separate compartments for invalids or consumptives travelling in search of health. The destruction of the sputum is, in his opinion, the main point to be aimed at.

FOREIGN UNIVERSITY INTELLIGENCE.

Bonn.—Dr. Fritz Roll, assistant in the Botanic Gardens, Würzburg, has been appointed Extraordinary Professor of Botany.

Digitized by Google

Freiburg.—Dr. Max Knies has been promoted to the rank of Extraordinary Professor.

Gratz.—Dr. von Wagner of Vienna has been appointed Extraordinary Professor of Mental and Nervous Diseases.

Lausanne.—Dr. H. Stilling of Strasburg has been appointed Professor of Pathological Anatomy.—Dr. Bourget of Geneva has been appointed Professor of Materia Medica and Therapeutics.

Rostock.—Dr. Berlin of Stuttgart has been appointed to the chair of Ophthalmology, vacant by the resignation of Dr. von Zehender.

Tomsk.—Dr. Sadoven of St. Petersburg has been appointed Professor of Physiological Chemistry. There are thus two professors of chemistry already in this newly-established university, which at present possesses only a portion of one faculty—the medical, Dr. S. Zalêski having charge of the general and medical chemistry.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. M. Perrin, Professor of Operative Medicine in the French Military Medical School of Val-de-Grâce; Dr. Marcantonio Barba, formerly Professor of Surgery in Messina.

ACCORDING to a telegram from Cape Town the Colonial Secretary, in reply to a deputation requesting information in regard to the Robben Island Leper Hospital, said that the anxious care of the Cape Government had long been devoted to the matter of leprosy generally, with the result that the disease in the colony had remained stationary, whilst the condition of the lepers themselves had greatly improved. The accommodation for lepers on Robben Island was vastly superior to that which they could obtain in their own homes. The stay of the patients on the island was voluntary, and relatives were continually permitted to visit them. The Government had for some time past been considering measures for effecting further improvement in the treatment of lepers and for their compulsory segregation under the Leprosy Repression Act.

FROM statistics compiled by the Egyptian Sanitary Department, it appears that in all the principal towns in the Delta, excepting Damietta and Rosetta, the death-rate exceeds the birth-rate from the end of May to the beginning of August, during which period the Nile water is most impure, owing to the lack of current. At that season the inhabitants of Damietta and Rosetta use water stored in cisterns, owing to the brackishness of the river water. This would (says the correspondent of *The Times* at Cairo) point to the necessity of adopting measures for purifying the Nile, upon which Egypt is dependent for her water-supply.

THE Italian Medico-military Office will shortly issue its report as to the sanitary condition of the army during 1887. The statistics collected from every branch of the service show a considerable improvement, we understand, over those of 1886. Admissions into hospital, which in 1886 had been 798 per 1000 of the force under arms, was reduced in 1887 to 760 per 1000. The mortality for the latter year, moreover, was 8·74 per 1000, as against 9·31 per 1000 for 1886.

WE very much regret to learn that Mr. Eustace Hill, son of Dr. Alfred Hill, medical officer of health for Birmingham, who has been serving as one of the resident medical officers to the Borough Infectious Hospital during the present severe epidemic of scarlatina, is himself suffering from the disease, and has exhibited serious symptoms. We sincerely hope that his condition will speedily improve.

WE understand that the Anglo-American Continental Medical Society, recently formed, will hold its first meeting in Paris on Monday, the 30th inst., when Sir Spencer Wells will preside, Professor Ball acting as vice-president. The meeting will be followed by a dinner.

THE first meeting of the Obstetrical Society of London for the coming session will be held on the evening of Wednesday, Oct. 2nd, at eight o'clock, at the Society's library, 54, Berners-street, next door to the rooms recently vacated by the Royal Medical and Chirurgical Society.

Pharmacology and Therapeutics.

NAPHTHALIN IN TYPHOID FEVER.

DR. C. SEHRWALD has made some bacteriological experiments in Prof. Rossbach's laboratory, from which he draws the following conclusions:—1. Naphthalin retards but slowly in the temperature of a room the development of the bacilli of putrefaction of fæces, and of typhoid. 2. Naphthalin finely powdered and well spread, or in solution and continually shaken, has its disinfecting power increased. 3. In a temperature of 98° the effect of naphthalin is much more powerful, which makes it highly probable that it is chiefly in its gaseous state that it destroys the germs. 4. Gaseous naphthalin in solution has more effect on aerobic than on anaerobic bacilli, and more on germs cultivated in a solid medium than on those cultivated in liquid. 5. The conditions for the full effect of naphthalin are much more favourable in the intestines than in the test-glass. 6. Naphthalin added to fæces decreases their germs by about a half, but, administered internally, it first decreases them to one-third or even a quarter; after this, however, their number rises again almost to its original figure. 7. Against the bacilli of typhoid stools naphthalin is considered still more effective, and decreases the number of the germs even to one-tenth. 8. The administration of naphthalin should be commenced at the very beginning of typhoid fever. 9. As calomel affects some of the fæcal bacilli, while others are more readily destroyed by naphthalin, it is best to give, whenever possible, both drugs combined.

MERCURIAL INUNCTIONS IN GLANDERS.

Dr. Gold publishes in the *Meditsinskoë Obozrênie* a detailed account of a case of glanders which was successfully treated by a prolonged course of mercurial inunctions. The patient was a young peasant, and though he was unable to trace his illness to any contact with glandered horses, experimental observations on guinea-pigs proved quite clearly that he was suffering from glanders. Half a drachm of mercurial ointment was rubbed into the skin twice a day, and the condition of his mouth properly attended to. He was also kept on highly nourishing diet. The tumours on different parts of the body were opened, and in some cases the edges of the wounds pared or touched with the actual cautery, antiseptic dressings being employed throughout. No less than sixty-eight frictions were employed, and the patient was kept five months in hospital before being discharged cured. The good effects of the treatment began to show themselves after twenty inunctions, the tumours becoming softer and the fine crepitation in the lungs disappearing. Dr. Gold points out that no reliance should be placed on the denial of patients of having had to do with diseased horses, the only sure guides to a correct diagnosis being bacteriological observations and the experimental infection of animals with the purulent matter from the tumours. Again, he thinks this case shows that even very severe cases of glanders may sometimes be treated successfully by a persevering employment of mercury, either by inunctions or hypodermically.

QUININE COMBINED WITH MERCURIAL INUNCTION.

Dr. Dymnitski records in a Polish medical journal the treatment of 178 cases of syphilis by means of quinine together with mercurial inunction. In some cases the quinine appeared to enhance the value of the mercurial treatment to a very remarkable extent; in others it appeared to be of no advantage. This method of treatment was most successful where

Digitized by Google

considerable variations of temperature, pulse, and weight existed. Thus it was found that in the cases where the treatment was decidedly successful the temperature was subject to a variation of 1·5° C or more, the pulse varied at least 26 beats, and the weight at least 10 lb. On the other hand, in the cases where this treatment was not successful, the temperature did not vary more than 1·2° C., the pulse not more than 18 beats, and the weight not more than 8·3 lb. The quinine was given in doses of from fifteen to twenty-two grains per diem. In many of the successful cases there had been a good deal of ulceration; this rapidly improved, the temperature fell, and the general condition underwent a marked improvement; but if the quinine was stopped the patient often became worse again. It should be said that care was taken to exclude cases in which there were any traces of malarial fever.

PEROXIDE OF HYDROGEN IN NECROSIS OF THE JAW.

Dr. A. Lohmann of Cassel communicates to the *Deutsche Medicinische Wochenschrift* several interesting cases from his dental practice. The first was that of a woman of thirty-two years, suffering from necrosis of the left lower jaw. A sequestrum with both bicuspids was completely separated, and without trouble or pain removed; the posterior portion, which still contained a molar, was freely movable and full of pus. After several injections of peroxide of hydrogen the discharge of pus entirely disappeared, the gum regained a healthy colour, and in about a fortnight the patient was quite cured. The second case was that of a civil engineer, twenty-six years old, whose left upper jaw was diseased. After removal of the sequestrum, which contained the last tooth and a bicuspid, peroxide of hydrogen was injected into the diseased alveolar processes at once and several times during the following days, and in a week the patient was completely cured. The author has even cured a case of alveolar pyorrhœa by this method.

RUBBER BANDAGE IN INDIGESTION.

Dr. Wettendorfer, while using a Martin's rubber bandage, applied round the waist in a case of chronic eczema, became aware that this treatment seems to be capable of acting beneficially on the digestive organs, curing gastric catarrh and the sense of oppression complained of by dyspeptics, and, as a result of this action, improving in a marked degree the digestive functions. How the bandage acts Dr. Wettendorfer is unable to say, further than that he supposes it is by exerting a mechanical pressure on the organs of digestion, and possibly by causing the bodily heat of that region to be retained. As to the particular classes of cases in which the rubber bandage is suitable only further experience can decide. The bandage should be worn for about an hour after meals, and should be applied over a surface about ten inches in depth.

SALIDAGO VIRGA AUREA (GOLDEN ROD) AS A DIURETIC.

Dr. Theodor Clemens of Frankfort, in a communication to the *Allgemeine Medicinische Central Zeitung*, once more recommends golden rod (Salidago virga aurea latifolia) as a diuretic, following in the footsteps of Ettmüller, Rademacher, and Mascarel, and correcting the mistake of Mascarel, who had looked upon the plant as a new remedy. Dr. Clemens praises this drug above all other diuretics, having relieved or cured a large number of patients by its administration. When there has been difficulty in obtaining it from pharmacists, he has frequently gone out into the woods and gathered the plant, and made preparations of it himself for his patients.

ANTIFEBRIN IN TONSILLITIS.

Dr. Sahli has found, both from personal experience and from numerous observations on patients, that moderate doses of antifebrin will almost invariably give great ease in cases of acute tonsillitis, thus allaying the distress of the patient and enabling him to swallow food, stimulants, or medicine. The dose he employs is seven and a half grains, which he usually orders in a mixture with spirit and syrup, which must be shaken up before being taken. This is sufficiently agreeable to be taken readily even by children. Dr. Sahli mentions that he has found great benefit from this treatment in scarlatinal sore-throat.

GUM BENZOIN IN ULCERATED LEGS.

Dr. Zitrin, writing in the *Voënno Sanitarnoë Dêlo*, strongly recommends the use of powdered Siamese gum benzoin as a local application for chronic ulcers of the leg. An ointment was used by Dr. Voskresenski for the same purpose; but Dr. Zitrin thinks the powder is preferable, especially on economic grounds. He ascribes the beneficial action to the antiseptic and stimulating effect of the benzoic acid, of which the Siamese benzoin contains about 14 per cent.

WOOD ASHES IN WHITLOW.

Dr. Kappesser of Darmstadt has for many years treated commencing whitlow very successfully by making the patient hold the affected finger very frequently in a hot lye made by steeping a handful of fresh wood ashes in half a pint of boiling water. A rag soaked in the same liquid is also applied round the finger when it is not immersed in the lye. In this way the whitlow can be cut short, especially if the treatment is commenced as soon as the first symptoms of the disease present themselves.

EAUX BONNES.

BY DR. DOBREE CHEPMELL.

A LOVELY place, this Pyrenean hamlet, 2500 feet above sea level—one steep, wide street of hotels with a garden in its midst. On east and west, cliff-like hills, 1000 feet high, green and beech-wooded to their tops, with here and there a snowy *pic* peeping over the shoulders of its smaller brethren, as if to see what the world is doing in the shady gorge below. The sky hardly forms part of the picture, a turquoise velarium only, stretched across like an awning from the high crest of one green hillside to that of its *vis-à-vis*. Beneath, at the head of the ravine, surrounded by planes and lindens, in air soft and cool, without wind, without rush, stands the Temple of Hygeia, known simply as "La Buvette." Hither daily, from 5 A.M. till dusk, during the short thermal season of July and August, crowd pallid sufferers from Russia, Spain, Holland, America, with a very few English, to drink their prescribed measure of the Source Vieille. The temperature of this spring is 82° F. or thereabouts; it has a strong sulphurous smell, with little or no taste. In mineral ingredients the water is marvellously rich, and seems to be a very watery extract *à la* Liebig of all the Pyrenean strata. Besides the ordinary components of most sulphur springs, there are found here, according to the careful analysis made by Dr. Garrigou in 1876, elements such as lithium, cæsium, rubidium, glucine, cobalt, nickel, antimony, and arsenic in appreciable quantities. Nature in this instance has indulged with a vengeance and *à la barbe de la Faculté* in the most undeniable polypharmacy.

A century and a half back the Eaux Bonnes were practically unknown, but towards 1750 Antoine Bordeu and his son Théophile, both men of energy and acumen, and practising in the valley of the Ossau, drew attention to the remarkable cures effected by these waters in pulmonary complaints. Not only were men relieved of chronic catarrhs and cured of consumption, but also were the maladies of animals—horses, donkeys, and goats—in like manner favourably influenced by the sulphur springs. Since the days of the Bordeus the reputation of Eaux Bonnes has been on the increase. It is said that much of the virtue of Eaux Bonnes depends (and this is also the opinion of Dr. Leudet, a most competent authority) on the stability of the sulphurous ingredients. A silver coin, newly minted, will, if immersed in the water, remain bright for some time; whilst, when dipped in that of other sulphur springs, the metal tarnishes readily. If administered to a dog, the animal's breath will shortly blacken a sheet of blotting paper wetted with a solution of a lead salt, showing that the principal element is largely exhaled from the lungs. Most of the drinkers whom I questioned were suffering from chronic bronchitis or fibroid phthisis. They told me that at first the water produced a slight feeling of nausea, with, as the treatment proceeded, a marked decrease, and presently a total cessation, of mucous expectoration. One man, long a sufferer from bronchorrhœa, remarked, "I no longer spit, nor even blow my nose, and I am very constipated; but, on the other hand, I pass quantities of water." And such really sums up the immediate action of the Eaux Bonnes. Dr. Leudet calls them "*des eaux désséchantes.*" Dr. Cazenave de la Roche, in addition, urges their anti-parasitic virtues, and

Digitized by Google

backs his opinion by referring to the experiments of Froschauer and Niepce as proving the destructive power exercised by sulphuretted hydrogen on the lower forms of life. Whatever the theory as to the *modus operandi*, the fact remains that in certain kinds of phthisis—e.g., fibroid degeneration with profuse bronchorrhœa—the benefit is very marked, and in many instances the gain is almost immediately appreciable. During the three or four weeks of my stay, I noted with interest the progress of these bibulous ægrotants, and can testify to the rapidity of the uplift in health in many of the cases. The drinkers, whom I had seen on arrival crawling painfully up the incline leading to the Buvette, coughing, spitting, puffing, and groaning, in ten days' time began to mount with elastic step and with little apparent fatigue and distress, evidently looking forward with confidence to their *quart* or *demi-verre* of the tepid specific. The dose of the Source Vieille is small—fifty grammes (or a quarter of a glass, equal to an ounce and two-thirds) at the start, twice a day, an hour before meals, and this is slowly increased to 200 grammes three times a day. The maximum of 600 grammes, or 20 oz., daily is rarely reached and never exceeded. Each drinker purchases the privilege of quaffing *ad libitum* for twenty francs, payable to the *fermier* of the Sources, whose £6000 annual rent is easily recouped. Gargling, inhalation of the pulverised spray, and a certain amount of bathing likewise go on, but the *traitement sérieux* consists in the internal exhibition of the water.

For the benefit of the visitors (drinkers and abstainers) a fairly good band plays twice a day in the Jardin Darralde, the small Eden spoken of in the centre of the village. At night this Pyrenean Vauxhall is illumined *a giorno*, not by aid of gas or petroleum, but by some scores of electric lamps, the effect of which, as toned down by the foliage, is remarkably pleasant. The services of a neighbouring cascade with a fall of thirty metres have been requisitioned, and force equal to 150 horse-power, acting through a turbine on a Gramm-motor generates electricity enough to furnish 600 jets to the little town.

Eaux Bonnes is easily reached by rail through Paris and Pau to Laruns, but in fine weather better and more economically by the General Steam Navigation Company's boat from Irongate Wharf on the Thames direct to Bordeaux, and thence on by rail in seven hours to Laruns, the terminus of the branch line from Pau. A good road winds up the picturesque ascent and lands the traveller in three-quarters of an hour at one of the best of Pyrenean hostelries.

REPORT ON SANITARY MEASURES IN INDIA IN 1887-8.

TOGETHER WITH MISCELLANEOUS INFORMATION TO JUNE, 1889. VOL. XXI.

As the greater portion of this report consists of a summary of the information given in the reports of the Sanitary Commissioner with the Government of India and of the health officer of Calcutta, which we have already noticed at considerable length (*vide* THE LANCET, Jan. 12th, June 22nd, 29th, and July 6th), it seems unnecessary again to go over the same ground. There is, however, in the appendix a minute by Colonel Henry Yule, C.B., member of the Council of India, on the subject of sanitation in that country which is well deserving of notice. In it he has taken a review of the present position of sanitary administration in India, and has endeavoured "to form some estimate of the degree in which that administration can be regarded as adequately discharging the duties of our Government in cherishing the health of the troops, in protecting the population from the ravages of epidemic disease, and in raising the standard of public health, as well as to consider what steps are practicable in order that those duties may be more effectually performed."

In 1864, in accordance with the recommendation of the Royal Commission appointed in 1859, to inquire into the subject of barracks and hospitals, the Government of India appointed sanitary commissions in the three Presidency towns, consisting of a civil officer as president, a medical officer as secretary, and a second medical officer and two military officers, one of them an engineer, as additional members. Their duties were "to give advice and assistance on all matters relating to the public health, such as selection of new stations and the sanitary improvement of existing stations and bazaars; to examine new plans for barracks and hospitals; to advise on the laying out of stations and bazaars, the sanitary improvement of native towns, the prevention and mitigation of epidemic diseases, and generally to exercise a constant oversight on the sanitary condition of the population, European and native; to report on the prevalence, causes, and means of preventing sickness and disease." In cases where the construction of remedial works was necessary their functions were to be consultative only, but in other cases they were also to be administrative. In less than two years, however, the Government of India abolished this commission, substituting for it a single officer as sanitary commissioner, with a medical officer as secretary. Colonel Yule states that when this change was carried out the Government "nominated to the position of sanitary commissoner an officer who, it is believed, had given no previous attention to sanitary questions!"

The Royal Commission above referred to stated the average mortality of the European soldiers in India prior to 1859 to have been 69 per 1000, and recorded their opinion that it "could be reduced to 20 per 1000; whilst a hope might be cherished that if the time should ever arrive when India should be freed from the general prevalence of malaria due to local causes, the mortality would come down to one-half of the rate just named." Colonel Yule states that the first of these anticipations has been more than realised, the death-rate in the last four years having been under 15 per 1000. He does not say directly that this has been the result of the measures adopted on the recommendation of the sanitary commissioners, but he has failed to point out that a considerable amount of the reduction may have been due to the altered conditions of service consequent upon the old local European force having been replaced by the regular army. We do not in the slightest degree undervalue the good work in sanitation which has been going on steadily in India during the last thirty years, but we feel it our duty to point out this other very important agency which has at the same time been in operation. But while there has been this remarkable reduction in the mortality, there has been no corresponding decrease in the admissions into hospital and the proportion constantly non-effective from sickness, the former amounting to 150 per cent. annually, and the latter averaging 71 per 1000 of the strength. Colonel Yule attributes this in a great measure to "the increased proportion of young soldiers, due to recent changes in the conditions of service. Such ratios render it imperative on those who are responsible for the health of the army to spare no effort, whether in discovering the causes of so great an amount of illness, or in removing or mitigating these causes when ascertained." He calls special attention to the increase in the death-rate from enteric fever and in the prevalence, in some districts of India, of intermittent fever as deserving of careful investigation. He also notices the diet of the soldier as an important element. It appears that in 1883-5, on a strong representation from the Army Sanitary Committee, it was made a subject of special investigation; but this does not seem to have been followed by any practical improvement. Indeed, in connexion with this question Colonel Yule gives an instance of how things are *not* done. In an extract from a resolution of the Government of Bombay "it is mentioned that the sanction of the Government of India had then been obtained to the 'issue of a free ration of cocoa to men quartered in the Ghorpuri barracks before going on parade in early morning or on sentry after midnight, as an experiment.' I have not found any record of the result of the experiment, which, *primâ facie*, strongly commends itself for adoption. In the return of reports on the subject of diet and daily meals from upwards of one hundred officers, which accompanied the India Government's letter of Aug. 7th, 1885, above quoted, I can find no one instance of cocoa being supplied." Some recommendations were at the same time made on the subject of clothing, on which Colonel Yule observes: "It would be well to know if a recommendation so obviously calling for attention has been followed up and become a rule general in India." We would venture to suggest this question as deserving of the attention of the Council of India, of which Colonel Yule is a member. He also points out the necessity for improving

Digitized by Google

the drainage and general sanitation of the country surrounding military stations in unhealthy localities, and the importance of locating a larger number of troops at the hill stations. To this latter subject considerable attention has been already paid, nearly one-third of the European force being thus quartered, with manifest advantage to the health, vigour, and efficiency of the troops. Colonel Yule brings specially to notice the great importance and necessity for some measures to reduce the amount of inefficiency from venereal disease. "The immense proportions of the evil must greatly affect the efficiency of the troops, whilst its nature is degrading to their character. No duty can be more incumbent—whilst, I fear, none is more difficult—than that of abating this mischief." After some remarks on the high death-rates in some of the Indian gaols, and on the mortality in the civil population arising from mitigable or preventable disease, he summarises the insanitary conditions under three heads: (1) Impure water-supply; (2) imperfect removal of filth and polluted surface; (3) a subsoil either polluted by the continual infiltration of surface impurities or saturated with moisture and unrelieved by drainage. In view of these evils the Government of India has expressed the opinion "that the time has now come for the prosecution of sanitary measures on a more systematic plan than has hitherto been adopted as a rule." This seems to involve increased expenditure on water-supply and drainage works; and with a view to efficiency in these respects, the provision (1) of the advice and aid of experts, and (2) greater facility in raising the necessary funds. Into the details of these, however, we cannot enter. Colonel Yule observes, "We have had reports, statistics, and suggestions for a quarter of a century, but taking a broad view of amelioration in the health of the country, the advance cannot be said to have been other than small. It is absolutely necessary that a new and large step forward should be made." Colonel Yule, in concluding his valuable minute, bears very gratifying testimony to the work done by Dr. John Sutherland during the many years he was a member of the Army Sanitary Committee, and from which he has recently retired. "The amount of Dr. Sutherland's work in this kind has been immense. But in quality and value it has been as great as in amount." He points out the great importance of a successor to him being appointed. There seems to be some difficulty raised by the India Office with regard to the payment of a member. "But it will be in reality maintaining an old appointment which has been of the highest value to the British army and to the State in India, and the cessation of which would be a deplorable misfortune." We trust that this strong protest may avail, and that we shall not have to suffer from a wretched system of saving a paltry sum of money at the expense of efficiency.

PRACTICAL OBSERVATIONS WITH REGARD TO THE PASTEUR TREATMENT.

A CORRESPONDENT, Mr. Harry Watts, of the London Hospital, forwards us the following interesting particulars concerning the method pursued at the Pasteur Institute:—

I have recently returned from Paris, having gone thither to take charge of patients who had been bitten by a rabid dog at Henley-on-Thames. During my daily attendances at the Pasteur Institute I have had many opportunities (through the kindness of M. Pasteur and his staff) of seeing the entire working of the Institution, and also of noting the treatment of some 200 patients who were at that time under care. Amongst this number were about a dozen English patients who were under my close and constant observation. Pasteurism does not appear to be even yet thoroughly understood by a large proportion of English practitioners, consequently patients are frequently sent over there to submit to the treatment without the slightest necessity, and so have to return to England uninoculated, and more or less dissatisfied with their medical attendant, who has thus unintentionally sent them on an unsatisfactory errand. For instance, one patient was sent over some three weeks after he had been bitten, who stated that the dog was still living at the time he left England; now it should be generally known that a rabid dog cannot exist for more than four, or at the most five, days after the biting stage of the disease has been reached. This M. Pasteur has conclusively proved; also that it jeopardises the successful issue of the treatment to a vast extent to allow so long a period as three weeks to elapse before this preventive treatment is adopted. Another rule which should be borne in mind is that when possible the head and neck of the rabid animal should be sent to the institute with the patient, for although on post-mortem examination the contents of the animal's stomach may be accepted as generally pathognomonic of rabies, yet M. Pasteur prefers the more scientific proof, which he obtains by inoculating a healthy dog with the virus taken from the medulla of the dead animal and producing the usual sequence of hydrophobic symptoms. In those cases where the head is not obtainable, the patient should then take with him the certificate of the veterinary surgeon who performed the post-mortem examination on the rabid animal, to the effect that it died from or was suffering from rabies. All the inoculations are performed in the flank, the regions just above the iliac crests on both sides of the body; female patients would therefore save themselves annoyance and the operator much time by making a vertical slit about six inches in length in their dress and underclothing, coinciding with the regions above named. It has been stated in the daily press that Pasteur's treatment is painless; this, however, is not quite correct. True it is that some patients are affected by it more than others, and children appear to feel it the least of any; their objections seem chiefly directed to the passage of the hypodermic needle. I have seen strong, well-developed, muscular men doubled up with the pain caused not by the needle only, but by the inoculated virus itself, and which the patients, almost unanimously, described as feeling "like corkscrews going down your legs." It is curious how similarly, though varied in degree, the different patients are affected, some feeling it more at one time than at another. I was much struck by this on one occasion when the virus was used at its strongest—viz., only two days old, and at the termination of the treatment. It then affected a labouring man in my charge more than at any previous time, whilst another of my patients, a somewhat neurotic lady, stated that at no previous inoculation had she experienced so little discomfort and pain; the same amount of virus appeared to be injected and it was of the same strength in both cases, and at exactly the same stage of the treatment.

Whilst observing the cases under treatment, one could not fail to notice that the same train of symptoms follows more or less markedly in every patient, man, woman, or child. Briefly they consisted of: 1. An initial stage of fever followed by varying degrees of prostration, and lasting from two to five days. 2. Some amount of formication, which is generally limited to the lower extremities; together with this is a feeling of intense weight in the legs, accompanied nevertheless with a desire to walk, and in the gratification of which the patient's best efforts fail to satisfy. 3. About the eighth day there is a pause, and, except for the tenderness in the sides at the inoculating area, there is but little to complain of, the former symptoms having for the most part subsided. 4. By the tenth or twelfth day, however, fresh symptoms arise, the chief among which is a sense as of constriction about the chest and throat, which is invariably complained of; some patients say they feel as if they had a sore throat and stiff neck, yet swallowing food or moving the head was unaccompanied by pain. On examining these regions there is nothing abnormal to be detected. These symptoms, as a rule, do not last more than a few days, though I have noticed exceptions.

The injected virus evidently sets up some amount of irritation in the system, though scarcely any at the site of the inoculation, which tends to produce a temporary hysterical condition. This was especially well marked in one of my cases, and most favourable results were obtained by treating her with carbonate of ammonia in doses of four or five grains thrice daily, as suggested by Dr. Silvester. The only cases which are refused treatment at the Pasteur Institute are those where the patient has been bitten by a non-rabid animal. As I have stated, such cases do get sent over to Paris; such persons are soon assured that they have nothing whatever to fear, and are free to return to England as soon as they like. The treatment being entirely prophylactic, there are no in-patients; neither is there any provision or room for such, the whole

Digitized by Google

building being occupied by splendid laboratories, cultivating rooms, &c.

In conclusion, it may be mentioned that wounds of the face are usually regarded as the most serious, and persons suffering from them are placed under treatment for a minimum period of twenty-one days, while trivial wounds of the upper and lower extremities are seldom detained for more than fifteen days.

THE SANITARY CONGRESS.

THE eleventh Congress of the Sanitary Institute was opened at Worcester on Tuesday, Sept. 24th, the attendance being somewhat small owing to the inclemency of the weather. After luncheon at the Guildhall, the members adjourned to the Skating Rink, where prizes and certificates were awarded for excellence in medical preparations, water filters, and other articles connected with sanitation.

In the evening Mr. G. W. Hastings, M.P. (President of the Congress), delivered an address at the Guildhall, and called attention to the intimate connexion existing between the public health and the sanitary condition of our houses and habitations. He urged the necessity of having proper appliances for the disposal of sewage, and expressed himself strongly in favour of placing the liquid sewage directly on the land. He then praised the excellent work done by the Plumbers' Company in London by training and registering skilled workmen. He next drew attention to the number of trades and occupations in this country which tended to produce disease and shorten life, and he insisted that it was the duty of the community as well as of employers to endeavour to remove the causes of unhealthiness in our industries. The general principles of sanitation would improve our drainage and remove other general causes of disease; but this would be to a great extent nugatory if industrial occupations were allowed to remain unhealthy. He also expressed his satisfaction at the enactment in the last session of Parliament of a measure for the notification of infectious diseases. It would have an immense effect in diminishing the spread of zymotic disease by enabling medical officers of health to hear of the first outbreak, and to take prompt measures for its suppression. No doubt some portion of the medical profession had raised objections to the measures; but the example of Edinburgh, a city in which the profession were remarkably influential and distinguished, showed that no real injury was done to them by notification. The system there, after years of trial, had been thoroughly approved by the profession. It was to be hoped that the sanitary authorities, both in town and country, would see the expediency of adopting, by every means which the Act provided, this easy and efficacious preventive against the spread of disease.

The Congress met again on the following day, and commenced the sectional sittings.

In Section I., "Sanitary Science and Preventive Medicine," Dr. G. Wilson, M.A., M.D., F.R.S.E., delivered an address on "The Policy of Prevention in some of its Social and Sanitary Aspects." He first glanced at the long roll of diseased conditions and premature deaths which depended on the laws of heredity—hereditary consumption, scrofula, gout, syphilis, cancer, hereditary insanity and nervous ailments, hereditary criminality, hereditary intemperance, hereditary vagrancy. Let them consider for a moment the multitudes of maimed and doomed offspring resulting from unsuitable or imprudent marriages, apart from cases of diseased or unhealthy parentage. Unthriftiness in marriage led too often to intentional neglect of the children, amounting to culpable homicide. It largely accounted for false thrift, under the name of infant life assurance, spreading its baneful influence even into innocent village communities. But public feeling was gradually being aroused to this enormity, and there were at last hopes of effective legislative interference. He doubted whether public opinion was sufficiently advanced to enforce a certificate of health on the part of persons about to marry; but he thought the time was at hand when some check should be put on the appalling waste of infant life which disgraced our civilisation by prohibiting marriages unless the man could produce reasonable proof that he was in a position to maintain a wife. As regarded all classes, it might be said that too early marriages, like marriages which took place too late in life, if not infertile, resulted in the birth of children afflicted with a lowered vitality. Physicians who had carefully studied the subject maintained that no woman should marry before twenty-one, and as regarded the other sex it might generally be said that the responsibilities of married life would be all the more safely faced if marriage were delayed until the age of twenty-five. But a vast amount of sickness might be averted, and a number of lives might be prolonged to mature age, if ordinary medical practice were based as much on preventive as on curative lines. The principal causes of disease were errors in diet, abuse of the luxuries of life, worry and overwork, idleness, want of self-control, irregular modes of life, errors in clothing, and, above all, intemperance. It was these causes that kept the ordinary practitioner busy, and which crowded the consulting rooms of the fashionable physician. It was true that diseases arising from impurities in air and water, unwholesome or insufficient food, and zymotic contagion still contributed largely to ordinary medical practice; but year by year they were becoming less prevalent. There was no disguising the fact that so long as the family medical practitioner continued to be paid to attend only on people when they were ill, and not to conserve the health of the household, there would be a constant drag upon public health progress. Curative and preventive medicine might go hand in hand for the promotion of public health and the abatement of human suffering. All that was required to effect the change was that the ordinary medical attendant should be paid by an annual stipend or retaining fee,—a system largely followed in India and other places abroad, and to some extent even in this country. Medical men were paid so much a year to attend members of friendly societies, &c., but unfortunately the majority of these appointments were scandalously underpaid, because they were regarded by medical men as stepping-stones to general practice. He next glanced at the studies of Pasteur, Koch, and Klein as developing the "germ theory of disease," and expressed his belief that the statistical results of M. Pasteur's treatment of hydrophobia powerfully supported his theory. Coming to the subject of the dangers attaching to our milk supplies, he said that in numerous outbreaks of scarlatina milk had been the medium by which the contagium of the disease had been distributed, and in many outbreaks of typhoid fever the disease had been propagated by washing out the milk cans or diluting the milk with sewage-polluted water. Now the State had enforced the provisions of the Cowsheds and Dairies Order, though it had been practically ignored in most parts of the country.

The President (Mr. Hastings, M.P.,) offered some remarks on the question of the milk supply. In India milk was always boiled before use, consequently India did not know what scarlet fever was. A discussion followed and the Congress adjourned.

THE INFECTIOUS DISEASE (NOTIFICATION) ACT AND THE PROVINCES.

THE Local Government Board have issued a circular to the urban, rural, and port sanitary authorities in England and Wales explaining the provisions of the Infectious Disease (Notification) Act, 1889, as published in our issue of last week. The present circular contains the following additional remarks as specially applicable to sanitary authorities outside the metropolis:—

It will be observed that, except as regards the metropolis, the Act will only extend to urban, rural, and port sanitary districts in which it is adopted by the sanitary authorities and the local authorities under the Act. The expression "port sanitary district" is defined by the Act as meaning the port sanitary district of London, and any port or part of a port for which a port sanitary authority has been constituted under the Public Health Acts.

The Act can only be adopted by a resolution passed at a meeting of the sanitary authority. Fourteen clear days at least before such meeting, special notice of the meeting and of the intention to propose the resolution must be given to every member of the authority. The notice will be deemed to have been duly given if it is either (*a*) given in the mode in which notices to attend meetings of the sanitary authority are usually given, or (*b*) where there is no such mode, then signed by the clerk of the sanitary authority and delivered to the member, or left at his usual or last-known place of abode in England, or forwarded by post in a prepaid letter addressed to the member at his usual or last-known place of abode in England.

When a resolution has been passed adopting the Act it must be published by advertisement in a local newspaper and by hand-bills, and

Digitized by Google

otherwise in such manner as the sanitary authority think sufficient for giving notice thereof to all persons interested.

The resolution will come into operation at such time, not less than one month after the first publication of the advertisement thereof, as the sanitary authority may fix; and upon its coming into operation the Act will extend to the district. A copy of the resolution must be sent to the Board when it is published.

The circular concludes as follows:—

The Board suggest that the sanitary authority should take into their early consideration whether, with a view to obtaining additional means of checking the spread of infectious disease in their district, it is not desirable that they should avail themselves of the power which has been conferred upon them of adopting the provisions of the Act.

HUGH OWEN, Secretary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kensington.—The parish of St. Mary Abbotts, Kensington, had a death-rate of 15·9 per 1000 living during 1888, and the concurrence of this low general rate with a correspondingly low zymotic death-rate is naturally regarded by Dr. Dudfield as a matter for congratulation. Measles was somewhat exceptionally fatal in Kensington, as indeed in London generally; and this leads Dr. Dudfield to discuss the question of isolation in hospital for this disease. As is well known, the Metropolitan Asylums Board have decided that they have no duty to receive measles cases, and having regard to the natural history of the disease and to the peculiarities of its onset and period of incubation, we incline to agree with Dr. Dudfield that there would be no public advantage in any general system for the removal to hospital of cases of measles. A number of other questions affecting metropolitan public health as a whole, rather than the special needs of Kensington parish, are discussed at considerable length in the report; but there is also much having local interest as to the work carried out by the officers of the vestry in the various departments coming within the supervision of the health officer, and we cannot but feel that this work is carried on in a manner that is worthy of imitation by some other metropolitan health authorities, and especially by such as distribute the sanitary considerations relating to their districts amongst multiple officers, all of whom are expected to advise on the same subject.

Ulverston Urban District.—The report on this district deals mainly with certain occurrences of disease, and a statement as to the principal sanitary circumstances of the district, together with an account of the matters as to which periodical inspections are made, no point of especial interest having arisen during the year. Dr. A. Thompson gives the death-rate from all causes as 18·1 per 1000, the zymotic rate being a low one, namely, 0·8 per 1000.

Ulverston Rural District.—In this rural area, also in Dr. A. Thompson's district, the general death-rate was 14·0 per 1000, and the zymotic rate 1 35. Amongst the deaths making up the latter group were 5 from diphtheria, together with the very suspicious entry of 10 deaths from so-called croup, which was certainly in large part diphtheria, although not of a very definite type. Fortunately the use of the term croup did not hinder inquiry with a view to the adoption of the needed means of prevention, and in one case, where sore throats had preceded genuine diphtheria, it was found that milk was the source of the infection. The disease seems to have started at High Wray, where the sanitary circumstances have been much neglected. These, it is to be hoped, will be forthwith remedied.

Ventnor Urban District.—Dr. Russell Woodford states that during 1888 the general death-rate of Ventnor was 12·8 per 1000 living, and that, if the deaths of visitors who came into the district with advanced disease be deducted, a resident rate of only 5·7 per 1000 remains. With such a rate there is obviously not much to record in the way of preventable disease, and the report is mainly made up of an account of the current sanitary work maintained. The water-supply of the town seems to be excellent; the sewerage is not referred to.

Derby Urban District.—According to Mr. Iliffe, the death-rate of Derby during 1888 was the lowest on record—namely, 16·3 per 1000 living on a population now exceeding 90,000. A full account is given of the infectious diseases which prevailed, beginning with a story of the introduction of small-pox from Sheffield. Scarlet fever was also widely prevalent. In all, 756 cases were reported, and of these 447 took place during the fourth quarter of the year, and all attempts to secure adequate means of hospital isolation broke down; indeed, only 20 per cent. of the total were so isolated. But Mr. Iliffe claims for notification some distinct power to reduce scarlet fever. Thus, judging from mortality, it would appear that during the nine years in which compulsory notification has been in operation, and including the whole of last year's epidemic, there was a total of 206 scarlet fever deaths; whereas in the preceding nine years the corresponding number was 562; and this although during the earlier of the two periods the population was distinctly less—indeed, at its close in 1881 it was nearly 9000 less than now. In all, 998 cases of infectious diseases came to notice during the past year under the compulsory notification clauses, and an account is given of the various steps taken in connexion with these to stay the spread of infection. Mr. Iliffe adds, regarding its working, that "it is scarcely possible for any law to be more loyally obeyed by all sections of the inhabitants." A new infectious hospital has for many years past been a great want in Derby, and we are glad to find that the construction of a very excellent building, of which plans are included in the report, is now rapidly approaching completion.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5284 births and 3117 deaths were registered during the week ending Sept. 21st. The annual rate of mortality in these towns, which had been 16·2 and 16·9 per 1000 in the preceding two weeks, further rose last week to 17·6. During the first twelve weeks of the current quarter the death-rate in these towns averaged 18·6 per 1000, and was 1·7 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 12·4 in Brighton, 12·7 in Derby, 12·8 in Leicester, and 14·2 in Halifax. The rates in the other towns ranged upwards to 22·7 in Plymouth, 25·3 in Sunderland, 26 9 in Newcastle-upon-Tyne, and 27·5 in Preston. The deaths referred to the principal zymotic diseases, which had been 512 and 529 in the preceding two weeks, further last week to 537; they included 279 from diarrhœa, 68 from diphtheria, 58 from scarlet fever, 57 from whooping-cough, 45 from "fever" (principally enteric), 29 from measles, and only 1 from small-pox. These zymotic diseases caused the lowest death-rates last week in Birkenhead, Birmingham, and Leicester, and the highest rates in Norwich, Plymouth, and Preston. The greatest mortality from diarrhœa occurred in Hull, Huddersfield, Salford, Newcastle-upon-Tyne, and Norwich; from scarlet fever in Blackburn and Plymouth; from whooping-cough in Bolton and Sunderland; and from "fever" in Norwich and Preston. The deaths from diphtheria included 44 in London, 5 in Salford, 4 in Manchester, 3 in Sheffield, 3 in Preston, 3 in Derby, and 2 in Birmingham. Small-pox caused one death in Sheffield, but not one in any of the twenty-seven other great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1171, against numbers increasing in the preceding twelve weeks from 559 to 1111; 128 cases were admitted to these hospitals during the week, against numbers increasing the previous four weeks from 98 to 196. The deaths referred to diseases of the respiratory organs in London, which had been 142 and 152 in the preceding two weeks, declined again last week to 142, and were 53 below the corrected average. The causes of 64, or 2 2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Sunderland, Oldham, Bradford, and in three other smaller towns; the largest proportion of uncertified deaths was registered in Liverpool, Salford, Huddersfield, and Sheffield.

Digitized by Google

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·5 and 19·1 per 1000 in the preceding two weeks, declined again to 16·4 in the week ending Sept. 21st; this rate was 0·6 below the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 9 5 and 12·3 in Perth and Leith to 17·9 in Edinburgh and 22·4 in Paisley. The 419 deaths in the eight towns showed a decline of 69 from the number in the previous week, and included 36 which were referred to diarrhœa, 15 to whooping-cough, 6 to "fever" (typhus, enteric, or ill-defined), 6 to scarlet fever, 6 to diphtheria, 5 to measles, and not one to small-pox; in all, 74 deaths resulted from these principal zymotic diseases, against 66 and 79 in the preceding two weeks. These 74 deaths were equal to an annual rate of 2·9 per 1000, which corresponded with the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 24 and 38 in the preceding two weeks, were last week 36, of which 10 occurred in Edinburgh, 8 in Dundee, 7 in Glasgow, 3 in Greenock, and 3 in Paisley. The 15 deaths from whooping-cough exceeded the number in the previous week by 2, and included 9 in Glasgow and 5 in Edinburgh. The 6 deaths from "fever," of which 3 occurred in Glasgow, showed, however, a decline of 5. Four of the 6 fatal cases of diphtheria and 2 of the 6 deaths from scarlet fever also occurred in Glasgow. The 5 deaths from measles, including 3 in Glasgow, were fewer by 4 than the number in the previous week. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 54 and 61 in the preceding two weeks, further rose last week to 66, but were 19 below the number returned in the corresponding week of last year. The causes of 49, or nearly 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·6 and 24·5 per 1000 in the preceding two weeks, further rose to 28·5 in the week ending Sept. 21st. During the first twelve weeks of the current quarter the death-rate in the city averaged 23·3 per 1000, the mean rate during the same period being 16·5 in London and 15·8 in Edinburgh. The 193 deaths in Dublin showed a further increase of 27 upon the numbers returned in the previous two weeks; they included 18 which were referred to diarrhœa, 8 to "fever" (typhus, enteric, or ill defined), 3 to whooping-cough, 1 to scarlet fever, and 1 to diphtheria. Thus the deaths from these principal zymotic diseases, which had been 33, 15, and 20 in the preceding three weeks, rose again last week to 31; they were equal to an annual rate of 4·6 per 1000, the rate from the same diseases being 2·2 in London and 3·7 in Edinburgh. The deaths referred to diarrhœa, which had been 26, 11, and 15 in the preceding three weeks, rose again last week to 18; and the deaths from "fever" showed a further increase upon recent weekly numbers. The deaths, both of infants and of elderly persons, exceeded the numbers returned in recent weeks. Twelve inquest cases and 9 deaths from violence were registered; and 52, or more than a quarter, of the deaths occurred in public institutions. The causes of 30, or more than 15 per cent., of the deaths in the city were not certified.

VITAL STATISTICS OF FRENCH TOWNS.

The French official statistics, issued annually by the Ministère du Commerce under the title of "Statistique Générale de la France," the volume relating to 1885 having just been issued, deal in considerable detail with the statistics of marriages, births, and deaths, but give no information concerning the causes of death in France, which is essential to supply explanation of the excess of mortality in that country compared with that which prevails in England and Wales. It is satisfactory, therefore, to find that much valuable information bearing on this branch of mortality statistics is now furnished by the Bureau de l'Hygiène Publique at the Ministère du Commerce et de l'Industrie in monthly and annual returns relating to those French towns which had at the date of the last census in 1886 a population exceeding 10,000 persons. In the first place, it is interesting to know that France contains 229 of such towns, which had in 1886 an aggregate population of rather more than nine millions of persons. When we bear in mind that in England and Wales we have a still larger aggregate population living in the twenty-eight large towns dealt with in the Registrar-General's weekly return, each of which had at the time of the last census in 1881 a population exceeding 70,000 persons, it becomes easy to realise how far smaller a proportion of the French population lives in large towns than is the case in this country. If we adopt the same limit for France, we find that in 1881 there were only 16 towns with a population exceeding 70,000, the aggregate population of which does not exceed four millions and a half, and considerably less than half the English population living in towns of the same size. The returns to which we refer deal, however, with all the 229 towns having a population exceeding ten thousand, and, as above stated, an aggregate population of rather more than nine millions. In comparing, therefore, the mortality of these 229 French towns, the majority of them being small towns, with that of the twenty-eight largest English towns, it must be remembered that such comparison should be favourable to the French towns, as, all other conditions being fairly equal, the death-rates of large towns almost invariably exceed those of small towns. The first annual return for these French towns has only just been issued, and relates to the year 1887. It should be stated that, although the return gives very valuable abstracts of facts, no calculated rates are given, and that any useful consideration of the facts necessitates the calculation of rates to population. This defect militates inevitably against the value of the return as a means of influencing public opinion in France in the direction of health-progress and sanitary reform. The marriage-rate in these 229 French towns in 1887 was equal to 15·4 persons married per 1000 of the population, which was fully equal to the mean rate in English towns in that year. The marriage-rate was 16·8 in the 11 largest French towns, and was somewhat lower in the smaller towns. Notwithstanding this fact of a marriage-rate fully equal to that which prevails in the English towns, the mean birth-rate in the 229 towns was only 25·1 per 1000, whereas in the twenty-eight English towns it was 31·2. The range of birth-rates in the French towns was not very wide, but it may be noted that the rate in the eleven largest towns was 26·1 per 1000, while, speaking generally, the birth-rate declined with the size of the town. Owing mainly, of course, to the low birth-rate, but also partly owing to the high death-rate, it is a fact that the deaths in these 229 towns in 1887 exceeded the births, whereas in the twenty-eight English towns the births exceeded the deaths by no fewer than 112,590, equal to an increase of 12 per 1000 of the estimated population. The death-rate in 1887 in the 229 French towns was equal to 25·3 per 1000 of the population, and exceeded by 0 2 the birth-rate in the same towns; in the twenty-eight largest English towns the mean rate in 1887 did not exceed 20·8 per 1000. Speaking generally, the death-rate among the French towns is no higher in the great than it is in the smaller towns. For instance, in the eleven largest towns, including, of course, Paris, the mean rate in 1887 was 25·3 per 1000, corresponding with the rate in the aggregate of the 229 towns. The only group of towns showing a marked excess included thirty-eight towns having populations ranging between 15,000 and 11,000; the mean rate in this group, with an aggregate population of 109,156, was 34·3 per 1000, the excess being in great measure due to the high rates in the following towns—Morlaix 41 5, Gentilly 55·7, and La Seyne 41·5 per 1000. These exceptionally high rates in such small towns may be susceptible of an explanation not readily suggested by the official tables. In Morlaix no less than 218 of the 609 deaths are returned as from unknown causes; 412 of the 775 deaths in Gentilly were of persons aged upwards of sixty years; and in La Seyne the 547 deaths included 238 of adults aged between twenty and forty years. Among the four largest towns it should be noted that the rate was 23·4 in Paris, 22·2 in Lyons, 29·2 in Marseilles, and 25·1 in Bordeaux; and that among the highest rates (again among the smaller towns) were 33·0 in St. Ouen, 38·4 in Ivry, and 38·7 in Bastia. Without at present going further into detail concerning the excess of mortality in French towns, the fact that the mean mortality during 1887 in the 229 towns dealt with in the official return we have had under review was equal to 25·3 per 1000, against 20·8 in the largest and most densely populated of the English towns, stands out conspicuously. In other words, disregarding the

Digitized by Google

difference in the size of the towns, which makes the comparison really unfair to England, the mortality in the French towns exceeded that in the English towns by more than a fifth, or 21·6 per cent. We note with satisfaction that the return now issued affords the means of analysing this excess of mortality in the French towns, and we propose on another occasion to deal with the age-distribution of this excess, and the diseases to which it is mainly due. At the same time, it may be hoped that, with a view to the education of public opinion on health matters in France, the French Government will ere long see the necessity of publishing rates of mortality as well as the bare facts, which have no value except for those who have the time and inclination to calculate rates for themselves.

THE SERVICES.

ARMY MEDICAL STAFF.—Brigade Surgeon William Folliott, F.R.C.S. Ireland, is granted retired pay (dated Sept. 25th, 1889).

VOLUNTEER CORPS.—*Artillery:* 1st Cheshire and Carnarvonshire: The undermentioned Acting Surgeons to be Surgeons:—W. Haining, M.D. (dated Sept. 21st, 1889); E. J. Lloyd, M.D. (dated Sept. 21st, 1889). — *Rifle:* 1st Volunteer Battalion, the Prince of Wales's Own (West Yorkshire Regiment): Acting Surgeon A. O. Wiley to be Surgeon (dated Sept. 21st, 1889).—1st Volunteer Battalion, the Leicestershire Regiment: Acting Surgeon R. B. Smith to be Surgeon (dated Sept. 21st, 1889).—2nd Volunteer Battalion, the Royal Scots Fusiliers: William John Lawrie, M.D., to be Acting Surgeon (dated Sept. 21st, 1889).—1st Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Surgeon A. Young resigns his commission (dated Sept. 21st, 1889).

Correspondence.

"Audi alteram partem."

THE DIFFICULTIES OF THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—If we admit, as many do, that the present times are not prosperous for the profession generally, there must be causes at work to produce such a result. Let us inquire and see if we can arrive at any of them. The general spread of education is one cause. At first sight it would seem to be natural that this would rather enhance the value of so useful a being as the family doctor. But in practice it is not so. The people are now fairly well instructed in physiology. They understand increased temperature; they know more, or imagine that they know more, of the A B C of medical matters than some doctors did forty years ago. Well, they or their children are in a febrile condition. It may be nothing, or a great deal; they assume at first it is nothing. So they go to Mr. Bolus, the nearest chemist, for a bottle of his effervescent saline mixture. They physic themselves and their children. If nothing is really the matter, the febrile temperature cools down and the patient is presently well. Or they do not even go to the chemist. Messrs. Tape and Thread, the drapers, sell a bottle of citrate of magnesia, granulated, at 6½*d.* This is better still. Then some of the family are below par. What is to be done? Why, send to one of the "Stores" or to the draper's and purchase Parrish's Chemical Food at one shilling a pound, cod-liver oil also, and so on. We might multiply this list a hundredfold. Thanks to newspapers and advertising, the superficial mysteries of the medical art are revealed. Sometimes disastrous results arise. They are discovered too late for remedy. A strangulated hernia has been dosed with aperients and castor oil till the damaged intestine has mortified. Or a case of diphtheria is only discovered when the patient is beyond hope and others of the family are infected; or a rheumatic fever, when the heart is damaged beyond repair; or enteric fever, undiscovered till perforation of bowel and death announce it; and so on. Every practitioner knows the evils of amateur doctoring. In this enlightened but feverish age every man strives to be his own doctor, lawyer, and theologian. The results are often very sad, but in the hurry of our present hectic existence unfortunately only too soon forgotten. This is, moreover, the age of quacks. True, Medical Acts of Parliament have been passed, but never was quackery more rampant than now. Not so much as formerly, it may be, in quacks themselves, but in the form of patent remedies and specifics for every disease.

In these advertising days, in medicine, as in everything else, people who know little or nothing of a subject, who presume ignorantly to address the public in the daily and weekly press, attract more notice than those who have devoted their lives to their particular work. It is a misfortune that in this country a very large amount of medical practice (and that the most easy and profitable) is lost to the profession by the fact that almost all chemists prescribe largely. This a great and crying evil. The practice is, instead of diminishing, largely increasing. This should be stopped. The chemist nearly always prescribes, but generally says, to cover himself, "If worse, take patient to a medical man." And so the medical man reaps all the hard work (often without being paid) and the chemist most of the profits. Then, again, hospitals, both special and general, take away largely from the proper, legal, and rightful profits of the profession. The public have a notion that they get advice and medicine of the highest character from the hospitals for nothing, but if they pay for it to the general practitioner they get a second-rate article. This is a bad system. Why not set up legal dispensaries for free legal advice, free places to get married in, free clothing establishments, free meat stores, &c., all paid for by subscriptions or rates? The fact is, the medical profession is gradually and surely committing suicide, and its career on the downward path should be promptly arrested. If we were true to ourselves (which we are not and never have been) the present increase in the profession would be insufficient to supply the needs of the public. But, if we go on working on the "sweating system" (for who sweats more, mentally and physically, than the hard-worked medical practitioner, night and day doing his best to preserve the health and life of the people?), often indeed without reward, then we shall be fools indeed. This idea, that medical services can be had for nothing, and so ought to be paid for at that price, is spreading. We are doing away with all professional reserve. We make everything plain, and it is valued accordingly. The more a profession is lowered in the eyes of the public the less respect it receives.—I am, Sirs, yours faithfully,

Sept. 1889. AN OLD DOCTOR.

NOTIFICATION OF INFECTIOUS DISEASES.

To the Editors of THE LANCET.

SIRS,—I think Professor Corfield must have been the subject of hyperæsthesia when he took personal offence at what I said in *The Times* regarding his previous letter. My remarks were directed against his letter, and not against himself, and I was particular in saying that many others had indited similar epistles, so that he had no need whatever to imagine that I singled him out for special condemnation. He says, however, that in classifying his letter with those of other medical officers of health with which Mr. Ritchie has been abundantly supplied, and still more in commending it as a good specimen of that class, I was guilty of bad taste, "to put it mildly." This addendum shows that the enormity of my guilt is wellnigh unspeakable, and I fear we must let it rest there. Professor Corfield allows that a reduction of 50 in the number of deaths in a town means the saving of 50 lives, whatever the previous number of deaths may have been. But his illustration of its relative importance in the two specified cases is not very felicitous. He says: "Of course, if 1000 deaths from a particular disease in a town are reduced to 950, and in another town 50 are reduced to 0, the same number of lives—viz., 50—are saved in each town; but to argue that the importance of the result is the same is very much like arguing that if one man has £1000 and loses £50, it is of the same importance to him as it is to a man who has £50 and loses all." This is to regard the reducing death-rate from the undertaker's point of view, which is naturally gloomy. Allow me to suggest a different illustration—viz., that of a man who, with an initial debt of £1000, pays it off by periodical instalments of £50. What I contend for is that in paying the last instalment, although the relief to his mind may be considerable from the fact that the debt

Digitized by Google

is at length cancelled, the effort required, the labour expended, is not necessarily greater than in paying the first. In reducing the number of deaths from 1000 to 0 there will be at least twenty times as much to do as in reducing 50 to 0, provided zero be a possible limit; and the reductions from 1000 to 950 and from 950 to 900 are by no means easier than other stages in the progress. It is by a regard to *remedial* sanitary administration, and not by a blind trust in any system of notification, that zymotic diseases will be most effectually stamped out. The case of Manchester, as referred to by Professor Corfield, still points the moral. But I fail to see that the dual system is likely to prove superior to the single system in repressing diphtheria. Huddersfield, Oldham, and Portsmouth have not been able to cope with epidemics of this disease one whit better than London has done under no system of notification. In 1887, when the death-rate from diphtheria was high throughout the country, it was, in London, 0·23; in Portsmouth, 0·34; in Oldham, 0·41; and in Huddersfield, 0·42. In Bradford, under the single system, it was only 0·05; in Nottingham, 0·03; but in Norwich 0·23, which, though high for the single system, was surpassed by no less than four towns under the dual system—viz., the three above-named, and Preston. I am, Sirs, yours faithfully,

Kingston-on-Thames, Sept. 21st, 1889. D. BIDDLE.

P.S.—In saying that *The Times* evidently considered his letter as conclusive, Professor Corfield seems to forget that concurrently with the letter in question appeared three others, and that two of these took the contrary part. One of the latter was from me, and has never been answered yet. I could not expect *The Times* to give me space for another letter, when it had already inserted four of mine on the same subject; and the discussion was practically closed there by the passing of the Bill. As a matter of fact, however, I did write again to *The Times*, replying to Professor Corfield by a sentence or two, but devoting the greater part of my letter to Dr. Farquharson, M.P., who, as shown by Mr. Corbett's recent letter to THE LANCET, was grievously mistaken as to facts connected with the medical profession in Kingston.—D. B.

"HINTS TO STUDENTS BEGINNING."

To the Editors of THE LANCET.

SIRS,—If "Experientia Docet" will excuse my correcting him I think he means that the term "physician" is used throughout nearly the whole of the English-speaking world as equivalent to medical practitioner. That is an intelligible proposition, but surely somewhat exaggerated, for though in the United States medical men in general practice are commonly called physicians, the word in the British islands is certainly generally used in a more restricted sense. Doubtless, St. Luke, the beloved physician, and Hippocrates himself were general practitioners dispensing their own drugs; but it is surely not now customary to style a man who prescribes and sells bottles of medicine for from 4*d.* to 5*s.* a physician, whether he be an L.S.A. or an M.D. Lond. It is quite true that the most divergent views are held among educated lay persons and amongst medical men themselves as to what is implied by the word. I may mention a few of these. 1. A physician is merely another term for a medical man, and is thus equivalent to the French *médecin*, the German *arzt*, or the Russian *vrach*, none of whom, by the way, are supposed to dispense. 2. A physician is an M.D. 3. A physician is a somewhat superior sort of medical man. 4. A physician is one who is at least a licentiate of some College of Physicians. 5. A physician must be a member of the London or Irish College of Physicians or a Fellow of the Edinburgh College, or must practise according to the rules enjoined on those holding those diplomas. 6. A physician is a consultant in surgery or medicine who takes no fee under a guinea.

If the first view be held, there is no term to distinguish the qualified proprietor of an open surgery or sixpenny dispensary from the F.R.C.P. who is physician to a great hospital. The second view is never held except by lay people. The third view is that which is held by a number of men, who put "physician" on their door-plates in the hope of making their patients think them superior to their opponents, who content themselves with the old-fashioned title of "surgeon." The fourth view, though it is held by many members of the profession, always seems to me rather senseless, for it can hardly be contended that an L.R.C.P.E. is far superior to an L.S.A.—or, at all events, to an M.B. The fifth view is the one, I think, which most nearly describes the way in which the term has generally been used in professional circles; and the sixth is confined to a small proportion of lay persons.

It is hopeless to expect to get any universally acknowledged definition of the word, and consequently it will, by a process of levelling down, soon come to be what "Experientia Docet" considers it now, the proper appellation of all medical men, and therefore no more distinctive in the profession than the term "esquire" is outside it. I cannot help hoping that this equalisation may take some time. I am, Sirs, yours truly,

September, 1889. THEODORE MAXWELL.

WHY DOES THE UTERUS CONTRACT DURING PREGNANCY?

To the Editors of THE LANCET.

SIRS,—The answer to the question, "Why does the uterus contract during pregnancy?" has so far eluded the investigations of physiologists, or at any rate text-books of obstetric medicine are of one accord in omitting to explain why such contractions occur, though they all present a clear description of the phenomenon itself, and assign to it an important position as one of the most trustworthy indications of the gravid state. In this connexion I venture to suggest that the cause of the continuous rhythmical movement is to be sought in the necessity for a more effectual removal of the blood contained in the utero-placental sinuses than would ensue if its return thence was entirely dependent on the normal forces by which circulation is effected in the natural venous channels. We have the authority of Playfair for the statement that the intermittent contractions occur every five or ten minutes, sometimes oftener, rarely at longer intervals, and that this alternating hardening and relaxation of the womb persists throughout the whole period of utero-gestation. We are all now familiar with the facts that the chorionic villi of the fœtus dip freely into the sinuses of the uterine wall, and that in this situation an exchange takes place between the fluids on the fœtal and maternal sides of the thin villous membrane which alone separates them; that the blood of the mother is thereby charged with excretory products from her offspring, and that the blood of the latter is purified and enriched by receiving oxygen and nutritive material from that of the former. The maternal blood is thus rendered especially impure at a spot where, owing to the anatomical arrangement of its containing structures, there is practical stagnation of the current. This necessarily leads, in time, to the excitement of irritation in the reflex centre governing the movements of the uterus, and as a result the muscular walls of this organ receive the summons to contract and expel the accumulation of carbonic-acid-laden blood as soon as this is gathered in amount sufficient to set the reflex mechanism in action. In this way the regular recurrence of the contraction is clearly to be explained; and also, I venture to think, the reason why almost similar movements of the womb continue when even death of the fœtus takes place a long time prior to its expulsion. In such a case the placental structures have naturally been developed in due course, and continue to be so until the accident happens which terminates the life of the embryo; the sinuses, consequently, continue to exist as blood receptacles, notwithstanding that no further interchange takes place between their contents and the fœtal blood. The supposition I advance also affords an explanation of the variation in rate of contraction noticed in different cases, for it is clear that accordingly as the maternal blood is drawn upon by one or more fœtuses, or by fœtuses varying in size, so will it be more slowly or more quickly depreciated in quality, and the occasion for its more or less rapid circulation in the uterine walls be called forth.

I do not propose to consider here the objections to the above hypothesis, which may be based on the existence of irregular contractions in uteri the seat of tumours other than those following conception. They will not, if duly credited with all the weight attributable to them, invalidate the theory; but their discussion would be out of place in this letter, which I am hopeful you may think worthy of being submitted to your readers.

I am, Sirs, yours faithfully,

Chudleigh, Sept. 12th, 1889. CHARLES H. WADE.

"ACUTE EPIGASTRIC PAIN IN PREGNANCY ASSOCIATED WITH ALBUMINURIA."

To the Editors of THE LANCET.

SIRS,—Mr. Bailey's accurately described case in your issue of the 14th inst. is worthy of remark. The whole clinical course of the illness might indeed be considered as typical.

In my paper on this subject published in THE LANCET, and to which allusion is made, I drew attention to some of the more leading features of this condition. One characteristic of the pain is apparently its severity, as evidenced by Mr. Bailey's patient and my own, who both considered the consequent labour pains as trivial in comparison. This alone should serve to differentiate it from dyspepsia. It is not constantly present, but rather assumes a rhythmic type of appearance, and it is always referred to as passing from the epigastrium through to the spine. Opium does not seem by any means a desirable or effectual remedy, and Mr. Bailey's observation as to the value of cocaine should be borne in mind. Should any practitioner meet with a similar condition, the question of induction of premature labour will always arise, and I can but think, seeing how rapidly amelioration of all symptoms follows the termination of labour, that much is to be said in favour of such a course. However, until more cases are published, and thus more data are at our disposal, no rules can possibly be laid down for treatment, and we must content ourselves with the scant comfort of knowing that it is unusual in occurrence, but dangerous.—I am, Sirs, yours faithfully,

Grosvenor-street, W. JOHN PHILLIPS, M.D.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Presentation to Mr. Reginald Harrison.

FOR some time past the members of the profession in this city have heard of the intention of Mr. Reginald Harrison, senior surgeon to the Liverpool Royal Infirmary, to leave Liverpool for London. While regretting very much the loss of so able and popular a *confrère*, his medical brethren feel confident that this step will tend to promote his interests and to raise him still higher in the estimation of the profession and the public. Arrangements have been made for presenting him with a testimonial at a complimentary dinner, which is to take place on Saturday, the 5th prox. A large number of subscriptions have already been received by Dr. Alexander Barron, the honorary secretary, and many have already intimated their intention of being present at the dinner. Mr. Harrison's connexion with Liverpool covers a period of thirty years, and has been throughout one of continued success.

The Royal Infirmary (Surgical Wards).

In Mr. Rushton Parker's wards there are at present two cases in which he has recently opened the bladder above the pubes, after the example of Mr. A. F. McGill of Leeds; one for enlarged middle lobe of prostate, which was excised, the other for ulcer of bladder in a tubercular subject in whom perineal section had been twice done without permanent relief. Both cases are so far entirely relieved, and doing perfectly well. The patient was placed in the inverted position, as adopted by Dr. Trendelenburg of Bonn, by which means the intra-peritoneal space was easily and safely reached, without distension of either bladder or rectum. These suggestions are of the greatest importance in the surgery of the bladder. Mr. Parker has also a case of fracture of the neck of the femur in a woman aged seventy-eight. She lies in a Thomas's hip splint, which for this fracture Mr. Parker has during more than ten years found to be all that its author claims for it in preventing non-union. In herniotomy, inguinal and femoral, Mr. Parker has in the last twenty-five cases practised the method of Dr. Macewen of Glasgow, in the treatment of the sac and the management of the wound; he thinks most highly of it. Another of his cases is that of a married woman aged thirty, who has had a tight stricture of the rectum for some years, supposed to be syphilitic. This has been excised entirely, and the patient has not had a day's illness since. For ordinary stricture of the urethra Mr. Parker employs internal urethrotomy with Maisonneuve's instrument. The patient is invariably kept in bed the night after for safety, but gets up next day, and often goes home or to work at once if he so desires. Mr. Parker recently removed a sarcomatous tumour blocking up the pharynx. The patient was a young man, and the tumour not apparently increasing in size. The removal was effected by the fingers and various forceps. The sense of smell and hearing, previously nearly gone, returned at once, and the patient has so far recovered without a bad symptom, in spite of profuse hæmorrhage. In a lad aged sixteen, an ossifying sarcomatous tumour of the left clavicle involving the outer half of the bone and some neighbouring soft parts was excised with rapid healing without fever or suppuration. No confidence is felt yet as to the ultimate result, but so far the patient can use the limb almost unimpaired. For chronic tuberculous lymph glands Mr. Parker performs excision frequently. Occasionally, but very seldom, he finds scraping sufficient, but many cases he has excised have been previously scraped by others, this proving often inefficient.

Liverpool, Sept. 24th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Scarlet Fever Epidemic.

THE scarlet fever epidemic in the city continues with unabated severity. The number of inmates in the special hospitals at the time of writing is 323; there are also 26 cases outside, in addition to 20 cases in the King's Norton and Aston infectious hospitals. Fortunately the death-rate is very low: thus the zymotic death-rate for last week was 1·7 and the general mortality for the city in the same week was 14·1. The Health Committee are placed in a difficult position in their efforts to cope with the infection, and are endeavouring to get more land for increased hospital accommodation. Some negotiations have taken place with the Lunatic Asylums Committee for a piece of land adjacent to the present site, and after prolonged deliberations a plot has been granted, subject to the approval of the Lunacy Commissioners. This is no time, however, for the play of red-tape officialism, for what is wanted is immediate and energetic action to cope with the rapid spread of the disease, and the treatment in a satisfactory manner of present cases. The staff at the three hospitals number seventy-six. Unfortunately nine of the nurses are *hors de combat* from the disease, and one of the medical officers, Dr. Eustace Hill, lies in a dangerous condition. Some correspondence has taken place between Mr. Chesshire and Dr. Bostock Hill in reference to the aggregation of patients suffering from this infectious disease; but the latter gentleman has shown that the acute cases have at least 1200 cubic feet space, which is probably much in excess of what they would get at their own homes. The other objection raised by Mr. Chesshire, that there is a high probability of the excreta from these patients spreading the disease by contaminating the sewers, need hardly be discussed in the light of modern knowledge of the disease. The President of the Sanitary Congress now sitting at Worcester made some pertinent observations as to the value of the new Act for the compulsory notification of infectious diseases. It is worthy of note that the health committee of this city are fully alive to the desirability of enforcing this Act at the earliest date consistent with its adoption by the city council; they will then have a valuable aid to their efforts to combat and suppress this epidemic. In the meantime there is no occasion for panic, and the utmost confidence is felt in the wisdom and discretion of the authorities.

Catapult Nuisances.

An instance of the danger of this juvenile nuisance was exhibited a few days ago in the case of a boy admitted into the General Hospital with one eyeball completely smashed by a missile from one of these dangerous instruments.

The Ear and Throat Hospital.

A special meeting of the governors of this institution was held on the 20th inst., to consider the proposal to erect a new hospital at which provision shall be made for in-patients as well as out-patients. The mayor occupied the chair. The report showed that there were largely increasing demands upon the usefulness of the hospital; it was stated that in

Digitized by Google

the five years ending 1888 the number of cases treated averaged 3198 per annum, as compared with 1730 for the previous five years. Promises of donations towards this object were recorded, and the plans appeared to be feasible and well calculated to meet the requirements needed.

Birmingham, Sept. 25th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

ALTHOUGH not strictly an association paper, the lecture which Mrs. Stopes of London delivered on Wednesday, Sept. 18th, on "Women's Dress Considered Physiologically and Psychologically," was as well attended as most of the sectional meetings, and was full of interest on this much-debated subject. Dr. Philipson gracefully presided, and Dr. Embleton joined in the discussion. Mrs. Stopes pointed out in her admirable lecture the various fashionable follies of her sex as regards dress, how many a girl goes out through the day dressed in tweeds and furs, and shivers at night in some of the various miseries of full dress. She said that no woman who wears high heels has the full use of her life or of her brain possibilities. When combined with tight shoes, as they generally are, her feet swell, and exercise becomes unpleasant and painful. She reclines on a sofa, becomes delicate, lames herself, and establishes in civilised Europe an imitation of the Chinese feminine foot. Mrs. Stopes says that the only place where high heels are really valuable is when we are walking up hill. She stated that she had some thought of taking out a patent for movable heels to be screwed on when ascending mountains, but the woman who wears high heels is perpetually walking down hill, and that one must remember the strain of a long-continued descent well enough to understand the effect of this injurious habit. Tight lacing she considers a national evil, and one to which the thousand nameless weaknesses and languors of the sex are often to be justly attributed. Last year, she said, when this subject was touched upon in the Physiological and Anthropological sections of the British Association, she mentioned that the female waist had decreased by two inches during the last twenty-five years. This may have been by the force of fashion during that period, inducing women to compress their figures and risk these evils, or it may have been through their having inherited a lowered vitality from mothers who have laced tightly in the past. The question is worthy, she said, of consideration whether women from any motive are justified in following fashion to an extent that not only tends to lower their own health, but to lower the physique of the whole nation. Any standards of taste recognised by the civilised world were based on the old statues of Greece, fashioned at a time when unhealthy and decrepit children were "put away," when there were no hospitals, and when exercise was a necessary part of education. But the statue of the Grecian Venus was five feet two inches and a half, and the size of the waist was twenty-six inches. "What modern Venus would not be horrified to appear in such proportions as these?" The remedy for these evils of fashion is to be looked for in the help of all women, and fathers, husbands, brothers of women, to elevate and develop a true standard of art-ideal, to "consider what forms of clothing are best fitted to develop the feminine frame naturally, healthily, perfectly." Mrs. Stopes' remarks were loudly applauded. During an interval in the work of the association, Sir H. Acland, K.C.B., accompanied by the Bishop of Newcastle and Dr. Embleton, visited the Newcastle City Hospital for Infectious Diseases. The whole arrangements, especially the provision of single bed wards for private patients, received the commendation of the visitors. Within the last few days a monument has been erected in Jesmond cemetery as a memorial of the late Dr. Luke Armstrong. The structure is of classic design, and is entirely built of polished Aberdeen granite. A committee of Wallsend workmen have purchased a complete ambulance carriage, built to their own order by Messrs. Atkinson and Philipson of this city, and having all the most recent improvements. In this good work the Tyneside workmen have followed the example of their Leeds brethren, and this commendable interest of workmen in ambulance work is increasing.

The Health of South Shields.

Dr. Munro, the medical officer of health for South Shields, states that during the past year the rate of infantile mortality was not only the lowest on record, but was under the average of England and Wales, and considerably under the rate ruling in the urban districts of England. The like held good of the death-rate from zymotic or infectious diseases. The gross death-rate was considerably below the average of the twenty-eight principal towns, and slightly under the average of the fifty smaller towns, although it was slightly above the average of England and Wales. The birth-rate on an estimated population of 69,500 furnished a rate of 36·1 per 1000, the lowest birth-rate on record. The gross death-rate was 18·201 per 1000 of the population, which was the lowest on record save that of 1881.

Northumberland and Durham Medical Society.

Under the presidency of Dr. James Murphy of Sunderland, this Society has taken a new departure in having a night devoted to a special address from an eminent member of the profession outside the Society—Mr. Lawson Tait. From what I can learn, there is likely to be a large gathering on the occasion at the Newcastle New Medical College. After the address on the 4th prox. a banquet will be held, open to all qualified practitioners.

Newcastle-on-Tyne, Sept. 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

Edinburgh Cow-houses and the Public Health.

MR. COOPER, the burgh engineer, acting under instructions from the magistrates, has recently been engaged in making a thorough inspection of the Edinburgh cow-houses. From his report it appears that they are almost without exception wanting in some of the essentials of a good sanitary condition. As this has a direct bearing on the milk-supply of the city, the details of the report afford ample food for reflection. Out of 220 byres in which are housed 2781 cows, only eight are "all but" in accordance with "the rules and regulations for cow-sheds, cow-houses, and byres"; that is to say, not a single one is so constructed that no exception can be taken, but there are eight which conform fairly well with rules and regulations; whilst, as will be seen from the following details of Mr. Cooper's report, most of the cow-houses are eminently unsuitable for the purpose for which they are used. He states (1) there are eight byres where the cubic capacity is sufficient, but having a number of more or less serious defects as regards structure, paving, draining, &c.; (2) sixty-two where the cubic capacity is insufficient, but the places are otherwise in fairly good order; (3) twenty-four where the cubic capacity is under standard amount (800 cubic feet for each animal), more than two-thirds of the same having more or less serious defects as regards the structure, paving, drainage, and cleanliness; (4) thirty-three where the cubic capacity is less than two-thirds, but more than one-half of the standard amount, besides having more or less serious defects as above; (5) thirty-four where the cubic capacity is less than a half of the standard amount besides having a number of more or less serious defects as above; (6) fifty-one where entire reconstruction ought to be insisted upon. When it is further considered that many of these byres are built in quite unsuitable localities, and that the cows in many of them are confined from year end to year end, and are under very imperfect veterinary supervision, it is not to be wondered at that when any epidemic does occur amongst them it is almost invariably attended with most disastrous results. Apart from all this, milk allowed to stand for even a very short period in such badly cared-for places must inevitably become deteriorated in quality, and will be more likely to collect various organisms than when the byres are well ventilated and cared for. It is greatly to be desired that the present scare about pleuro-pneumonia, accompanied as it is by a considerable drain on the ratepayers' pockets (through the public health department, by way of compensation for slaughtered animals), will call attention to the fact that by far the most economical plan

Digitized by Google

for both producers and consumers will be to build good cow-houses on proper sites. It does not pay any farmer to keep sickly cattle, and many of those whose byres are not in the worst possible condition would be incalculable gainers were they compelled to put up well-ventilated and well-drained cow-houses. The consumers of milk would gain in confidence if not directly in pocket.

Suggested Experimental Station.

Professor Chiene recently sent a letter to the Fifeshire local authority in which he offered to carry out a number of experiments on the inoculability of pleuro-pneumonia in cattle, especially with regard to the particular organism that is the cause of the disease. He thinks that if this could be found there might be some possibility of obtaining a protective virus. He asks the local authority to supply such a station (say, one of the islands in the Forth Inchcolm) and animals for experimental purposes. As his share he offers the use of his laboratory and his assistant to do the work. Such combinations have succeeded in France and in other countries, and there is no reason why equally good results should not be obtained in Scotland, not only in the case of pleuro-pneumonia, but also in the other diseases about the nature of which there is still any doubt.

Post-graduate Classes.

This year the post-graduate classes are not arranged quite as in former years. It has been found by experience that men coming up to study like to get something of everything and everything of one thing. The clinical and general classes are arranged as before, but some of the special courses are more elaborate and occupy a longer time than in previous years. For some of these classes a special fee is charged. How far the change will be acceptable to the graduates still remains to be seen.

Edinburgh, Sept. 23rd.

GLASGOW.

Report on an Insanitary Industrial School.

LAST WINTER an epidemic of a somewhat puzzling character, fully described in THE LANCET at the time, broke out in Abercrombie-street Roman Catholic Industrial School for Boys, Glasgow. The disease was of an obscurely febrile nature, associated in some cases with pneumonia. There were 23 cases and 4 deaths. After most careful investigation, the sanitary authorities of the city reported that the locality and its surroundings were not suitable for so large a school. The school managers and their medical adviser opposed this view, and resisted the suggestion that the school should be removed. A report now issued by Colonel William Inglis, the inspector appointed to visit the certified reformatory and industrial schools of Great Britain, quite bears out our local authorities. He states that this is not the first time that attention has been drawn to the sanitary condition of this school. In 1887 he reported that there was insufficient space for so large a number of children. In the previous year he reported the situation as unhealthy. In 1885 he said: "The school is very subject to epidemics," and referred to two during that year, one of small-pox and one of measles. In 1883 and previous years attention was drawn to the fact that the children when admitted were generally of a very feeble type, and that fresh air and healthy surroundings, with warm clothing, plenty of good food, accompanied by individual care and attention, were especially necessary for them. In view of such a serious report the managers have under consideration the removal of the school, but there is some difficulty in obtaining a site near Glasgow. "If this difficulty is not soon surmounted," states the inspector, "I see nothing for it but to close the school."

Glasgow, Sept. 23rd.

ABERDEEN.

The Health of the City.

DR. HAY, in his report for the month of August, says the health of the city has been very satisfactory. The death-rate from all causes—viz., 13·57 per 1000—is much below that of any previous month in the present year, and is lower than that of the immediately preceding month by 3·8 per 1000. The decline is chiefly evident in deaths among persons under five years of age and persons above sixty, and is due in part to a large decline in the miasmatic death-rate, which has fallen to 9·7 from 29·1 per 10,000 in the previous month. As compared with the same month in the previous ten years, the total death-rate for last month is distinctly the lowest, and is lower than the average by 2·85 per 1000. The epidemic of measles is now rapidly drawing to a close. In December last, twenty cases of measles were reported, and for the first five months of the present year the numbers increased steadily until in May 731 cases were reported. Then in June a decline set in, and for that month the number was less by 200, and in August only 73 cases were reported. The mortality from measles during August was high—viz., 1 in 8, the highest recorded in any month since the commencement of the epidemic. After an absence of a month, scarlet fever again returned, and a few mild cases were reported. The cases of whooping-cough were exceptionally small in number, while the number of cases of diphtheria and typhoid fever was slightly beyond the average, but nearly all of them were mild. At the end of the month there were only seven cases in the City Hospital.

Aberdeen, Sept. 23rd.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Amalgamation of the Dublin Medical Schools.

AT last the amalgamation scheme may be regarded as *un fait accompli*, all difficulties having been removed, and the new Schools of Surgery, Royal College of Surgeons, including the Carmichael College and the Ledwich School, will be an undivided centre of medical education. The new professors &c. will be elected about the latter end of October, and the winter course of lectures will commence as usual on November 1st. The Council of the Royal College of Surgeons have had many difficulties to encounter in carrying to a successful termination the scheme of amalgamation, and deserve the thanks of all interested in medical education in this city for their disinterested services.

The late Dr. Robert McDonnell of Dublin.

Some members of the profession have thought it advisable to have some permanent memorial of the late Dr. McDonnell, whose untimely decease they, in common with many of the community, so deeply deplore. It has been suggested that a marble bust and a portrait, to be placed in the Royal College of Surgeons, of which he was an ex-President, would be a suitable tribute to his memory. A committee, of which Mr. Austin Meldon, President of the College, acts as chairman, has been formed, and Mr. Anthony H. Corley will be the honorary secretary.

New Cavalry Barracks, Dublin.

The new barracks at Grangegorman, near the Phœnix Park, are rapidly approaching completion. The ground covers an area of twenty-five acres, and when some additional works, now under consideration, are finished, it will allow accommodation for about 500 officers and men, with the same number of horses. The dormitories will be well ventilated and supplied with the most approved sanitary appliances; while the recreation rooms will consist of a coffee- and reading-rooms, also fencing and lecture rooms. The cost of the barracks will be about £60,000. The recent cold weather has been felt greatly by the men under canvas in the Park, and it is contemplated that in a week or two one of the two regiments will be moved to the Royal Dublin Society's premises at Ball's Bridge for the winter; while the other regiment will be sent back to the quarters they formerly occupied in the Royal Barracks.

St. Vincent's Hospital, Dublin.

After serving for upwards of thirty years as visiting physician to St. Vincent's Hospital, Dr. Quinlan has relinquished his clinical duties, and has been appointed consulting physician to that institution. Dr. Quinlan retires in compliance with the regulation of the hospital, which limits the tenure of office of the members of the visiting staff to twenty-five years.

Pauperism.

The returns of pauperism for the June quarter of the present year, which have been furnished by the Local Government Board, show a decrease of 1185, or 2·6 per cent., in the average number of workhouse inmates on Saturdays during the quarter, and a decrease of 2228, or 3·4 per cent., in the average number of persons on out-door relief.

Dublin, Sept. 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Executions by Electricity.

AT a recent meeting of the Academy of Sciences, the Perpetual Secretary read a paper from Mr. Edison on the application of electricity in place of hanging as a capital punishment. In this report Mr. Edison compares the effects of the continuous currents with those of the alternative currents, and he gives the preference to the latter, as he believes that they will cause death without any pain whatever. He described some experiments which he had performed on several of his own workmen. To a question that was put to him, as to what time it would take to consume a body, Mr. Edison replied that the body would not be consumed, but that its temperature would only be raised by three or four degrees, and that the body would then remain as if mummified. Mr. Edison concluded his communication with the impression that death by electricity may be produced instantaneously and without pain. Mr. Edison's paper was referred to the sections of physics and of medicine, and M. Marcel Desprez, the eminent electrician, is to draw up a report on the subject.

Preventable Mortality in the French Army.

The authorities have been somewhat alarmed at the number of deaths in the army this summer caused by diarrhœa and typhoid fever. These diseases have been attributed to the imprudent ingestion of contaminated water, as well as to meat in a state of decomposition which has been distributed to the soldiers. In a report drawn up by Drs. Poincaré and Macé of Nancy, the authors recalled that contemporary science has demonstrated that there sometimes develop in alimentary substances of animal origin extremely active poisons, the nature and the genesis of which are hardly yet determined. These poisons, called ptomaines, originate in the course of putrefaction. It is to ptomaines and not to microbes that must be attributed the toxic phenomena which follow the use of stale sausages &c. The same authors have also found in a great number of alimentary preserves the presence of living microscopic germs. All preserves, even those that are well prepared, are, it would appear, susceptible of these alterations. Germs which are entombed in these boxes are struck with catalepsy, but they soon become revivified on being exposed to the air. It is therefore considered advisable that immediately a box is opened its contents should be used; when this precaution is not observed, and in spite of every possible care, the rest of the preserve becomes putrid with a rapidity much greater than that of similar substances freshly prepared. The conclusion is that in the alimentary hygiene of the soldier the use of preserves should be abandoned; at any rate, in time of peace. As for alimentary preserves in time of war, this subject is being carefully studied by the military authorities. Among other things, a new sort of compressed bread has been submitted to the Minister of War for examination. This compressed bread, which is manufactured with similar flour to that used for the bread in use among the troops, and without any other addition, takes the form of a thin cake, which is easily softened and broken. Soaked in water for a minute this cake, of 340 grammes in weight, is then exposed to the air for a quarter of an hour. The bread then resumes its original size and its excellent flavour of fresh aliment. This new bread is recommended as being far preferable to the biscuit of old, so fertile of gastralgia and diarrhœa, and which Chenu, the celebrated army surgeon, justly condemned when he asserted that biscuit is to bread what salt meat is to fresh meat, with this difference, however, that the stomach supports salt meat better.

Place of Origin of the Human Race.

M. de Quatrefages, who is a confirmed monogenist, entertained the Academy with the definite results of his researches. He fixes the north of Asia as being the seat of the origin of the three principal types of the human race—the white, the yellow, and the black. Asia has remained the home of the yellow race, Europe was invaded by the white race, and Africa by the proto-semites and the black race. The three types are to be found in the Oceanic Islands. The invasion dates from the tertiary epoch. On the other hand, America was peopled only at the quaternary epoch by the white race.

Civilisation and Disease.

At the same meeting M. Milne-Edwards presented, in the name of M. Certes, an extensive memoir, in print, entitled "The Protozoaires of the Mission of Cape Horn," accompanied by drawings of extreme delicacy. According to the author, there are no pathogenic microbes to be found at Cape Horn. The Fuegians did not know anything about small-pox, measles, scarlet fever, or diphtheria before the inroads of civilised nations. Before the visit of the mission even pulmonary phthisis was unknown. Tuberculosis only commenced to establish itself in the country since 1881. M. Certes has given the drawings of the rhizopodes, the infusoria, brought up from a depth of 7000 metres, by the naturalists of the *Romanche*.

Health of Paris.

Notwithstanding the influx of visitors from all parts of the world to see the great Exhibition, the public health of Paris is considered to be excellent. The municipal report of last week shows a mortality of 867, instead of 890 during the preceding week. The average weekly mortality for the five corresponding previous years was 893.

Paris, Sept. 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Society for the Promotion of Public Hygiene.

THIS Society has just held its fifteenth annual meeting at Strasburg. Its first sitting was held on the 14th inst. in the Town Hall, and was attended by 220 persons. The secretary of the Society stated that the number of its members was 1160. Dr. Krieger, of Strasburg, the chief medical adviser of the government of Alsace-Lorraine, spoke on the hygienic conditions and arrangements of those provinces. He mentioned that, since the regulation of the course of the Rhine, intermittent fever, which used to be very frequent, and which was followed by goitre and cretinism, had almost disappeared; among the troops garrisoned in Strasburg, for instance, it had sunk from 80 to less than ½ per cent. The chief event of the first meeting was a lively debate on the measures to be taken for the attainment of healthy dwellings. The chief speaker was Dr. Miquel, Burgomaster of Frankfort-on-the-Main, and one of the leaders of the great National Liberal party. He explained and advocated the proposals made by the committee appointed to study the question last year. The debate resulted in the acceptance of the proposals, which will now be laid before the Imperial Government. They are classified under four heads—viz., streets and sites, the erection of buildings, the construction of rooms for human habitation, and the use of such rooms. The second sitting was held on the 16th, and was opened by a lecture delivered by Professor von Ziemssen of Munich on Convalescent Homes. Among the various great advantages of such institutions he mentioned their economy, stating that the average cost of maintenance per patient in the Berlin and Munich hospitals was 2 marks 50 pfennigs (2*s.* 6*d.*) per day, and in the convalescent homes only 1 mark 75 or 80 pfennigs (1*s.* 9*d.* or 1*s.* 9½*d.*). In England, he added, the cost of maintenance in convalescent homes was only 1*s.* 4*d.* He recommended the example of the great convalescent home at Vincennes, which had recently established a branch home in Paris, in which the patients after leaving the home might spend two days looking for work. He recommended the establishment of homes in or very near cities for patients recovering from acute diseases, and of others in rural districts for chronic cases. This discussion was followed by a lecture of still greater interest and importance by Professor Heller of Kiel. Its theme was the prevention of tuberculosis, "the most dreadful and ravaging of all diseases." I much regret that space will not permit me to reproduce this lecture. The speaker was followed by Drs. Dettweiler, Cornet, and Wyss, all three well known as authorities on the subject. Dettweiler exhibited and recommended his pocket spittoon. Wyss went into details on the subject of the relation between the human race and the lower animals in the matter of tuberculosis, laying special emphasis on the fact that frequency of tuberculosis among the cattle of a district invariable goes hand in hand with corresponding frequency among the human inhabitants. The theme of the third and last day was railway hygiene, and was introduced by

Digitized by Google

Herr Wichert, Privy Councillor of Public Works in Berlin, in a masterly and exhaustive lecture on the construction of passenger carriages, the arrangement of the seats and bye-rooms (closets &c.), the construction of the seats and the furnishing of the compartments, the lighting, ventilation, heating, and cooling of the same, the arrangements for securing passengers against accidents, the regulations for the use of the seats, the arrangement of passenger carriages of special kinds and for special purposes or times, help in case of accident or illness, and, finally, disinfection. A lively debate followed, Wichert's opinion that the present system of lighting passenger carriages was sufficient, because it was not advisable to encourage people to injure their eyes by reading in trains at all, was met by the remark that one did not read novels only in trains, but also more important publications.

The Prussian Chambers of Physicians.

For the second time since the establishment of the Prussian Chambers of Physicians their representatives have been invited to take part in the deliberations of the highest medical official body in Prussia—viz., the Scientific Deputation for Medical Affairs. At the time when the said Chambers were organised the State granted them the right to be heard by the official authorities on certain general sanitary questions. Each chamber therefore received the right to send one representative to the Scientific Deputation and one to the chief medical official body of its province, and these representatives are permitted to take part in the deliberations, but not to vote. They are now regarded as extraordinary members of the Scientific Deputation, and are invited to take part in its deliberations once every year—viz., in November. The themes of discussion this year are to be the reform of the midwife system and the revision of the official text-book for midwives. These subjects will be introduced by Professors Olshausen of Berlin and Bockendahl of Kiel.

The Society of German Dentists.

The Society of German Dentists met at Kassel on the 15th and 16th inst. The main question discussed was whether the Society should resolve to form a union of guilds or a union of free societies, and the majority resolved to adhere to the former resolution of the Society and form a union of guilds. The Society numbers more than 300 members. Its next year's meeting will be in Leipsic. Hermann of Cologne demonstrated Humm's method of filling teeth with the help of a new sucking apparatus invented by the demonstrator himself, Rauhe of Düsseldorf, the filling of teeth with gold and gold tin, and Mueck of Berlin a new Charnier-lever apparatus, constructed by himself, for turning the axes of wry teeth, and other implements of the same kind.

Professor Anton Nuhn.

Professor Anton Nuhn, who died at Heidelberg lately, aged seventy-five, was, after Joseph Hyrtl of Vienna, the oldest German teacher of anatomy. He was one of the few anatomists of the past half century who made a discovery in descriptive anatomy. In 1845 he discovered the glands, now called by his name, at the end of the human tongue. He was also one of the first who studied the causes of deafness and dumbness anatomically. Among the other subjects on which he wrote, I may mention the connexion of the lymphatics with the veins, the structure of the skin papillæ, the secretion of the gall, and faulty structure of the heart. He was also the author of handbooks of surgical, practical, and comparative anatomy, and of a series of surgico-anatomical tables.

The Propagation of Phthisis.

There is a general agreement among medical men that the tubercle bacillus discovered by Robert Koch in 1882 is the germ of phthisis. Some are of opinion that this bacillus can settle only in the lungs of persons specially predisposed for its reception, owing to the presence of tuberculous disease in their parents, or to general inborn or acquired weakness in themselves. Dr. Cornet, one of Robert Koch's pupils, has been led by his investigation of the manner in which tubercle bacilli spread to a different opinion. He declares that tubercle bacilli are always to be found on the walls of rooms in which consumptive patients have lived, without the necessary care being taken for the removal of their sputum. He thinks that the spread of phthisis is due almost exclusively to the inhaling by healthy persons of tubercle bacilli emanating from the scattered and dried sputum of uncleanly consumptive patients, and that heredity and acquired predisposition are of quite subordinate importance. In order to settle the question, Professor Bollinger of Munich has made a proposal to the Bavarian Government. It is known that in prisons one-third or more of the inmates fall victims to phthisis. Bollinger proposes that one prison ward be as thoroughly disinfected as if cholera patients or plague patients had lain in it, that all prisoners suffering from or even suspected of tuberculosis be removed from it, that the sputum of those that remain be removed as Dr. Cornet prescribes, and that the ward be then observed for a length of time, with a view to ascertaining whether the cases of phthisis prove less numerous than before.

The Anatomical Society will meet in Berlin on Oct. 10th.

A joint-stock company for hygienic purposes has been founded in Berlin with a capital of 750,000 marks (nearly £37,500).

Professor Berlin, of Stuttgart, has been called to Rostock, as Professor of Ophthalmology and head of the University Eye Hospital, succeeding Professor Zehender, who retires owing to his advanced age.

Berlin, Sept. 23rd.

Obituary.

PROFESSOR RUDOLF VOLTOLINI.

PROFESSOR RUDOLF VOLTOLINI, whose death at Breslau we announced last week, was one of the first aurists and laryngologists of his time. His first writings on the treatment of diseases of the ear appeared about the end of the fifties in Virchow's *Archiv*, and in one of the earliest of them he described a new method of illuminating the organ of hearing and other cavities of the body. In 1860 he established himself as a private lecturer (*privat-docent*) in the University of Breslau. In the years immediately following he busied himself chiefly with the practical problem of making the new galvano-caustic method of operation available for the treatment of internal diseases of the larynx and the pharynx. In 1853 Middeldorff, guided by the physicist Gustav Kirchhoff, one of the inventors of spectral analysis, had showed how certain surgical operations could be performed better and more easily with the electrically heated wire loop, a discovery which became much more important when Victor Bruns of Tübingen proved the possibility of operating on the larynx through the mouth. Voltolini published the results of his studies and experience in 1867 in a book on the galvano-caustic method, and its application in diseases of the larynx. In 1868 he was appointed professor of otiatrics and laryngology at Breslau. The titles of his other most important writings are the "Examination of the Nose and the Pharynx," the "Diseases of the Nose," "Polypus of the Nose," and "Acute Inflammation of the Cuticular Labyrinth." He retained his mental powers unimpaired to the last, speaking and writing with great vivacity on question connected with the special subjects of his research.

DR. DE LEO, BEY.

AT the close of last week there died in Milan, on his return from Egypt, the Commendatore De Leo, Bey, the most distinguished Italian consultant in the dominions of the Khedive.

Dr. De Leo was a Sicilian by birth, his native town being Messina. Having qualified at the Neapolitan school just fifty years ago, he graduated in medicine, and was on the threshold of his career when the disturbed condition of his country drove him, like many others, into exile. He made Egypt his home, and threw himself with energy into professional life. He speedily acquired an extensive *clientèle*, not only among his compatriots, but in the European colony generally. He became body physician to the two Viceroys, Abbas and Ismail, and won their confidence in many ways by his medical skill and by his sound, cool judgment as an adviser and a friend. The influence thus

Digitized by Google

acquired he employed on behalf of the foreign population, British and French as well as Italian.

On the fall of Ismail he asked and received permission to retire from court, for reasons of advancing age. He still, however, practised as a consultant, and still interested himself in the European community, liberally devoting to charitable objects a portion of the fortune he had honourably amassed. His popularity, particularly with his compatriots, was immense, while the decorations of Commendatore of the Crown of Italy, and Officer of SS. Maurice and Lazarus, received from the Italian Government, attested his country's esteem for him. He possessed also many foreign distinctions, and was corresponding member of numerous scientific bodies in Italy and elsewhere.

"Always holding aloof," says one who knew him well, "from the political imbroglios of Egypt, he occupied himself with medicine pure and simple, and reflected honour alike on science and on himself. He was an ardent lover of his country, and allowed no year to pass without a visit to Italy, sometimes for many weeks." It was on one of these sojourns that he suddenly passed away, at Milan, as we have said, in the Albergo dell'Europa.

J. ADOLPHUS SMITH, M.R.C.S. ENG.,
SURGEON-MAJOR, ARMY MEDICAL STAFF.

SURGEON-MAJOR JAMES ADOLPHUS SMITH died at Bhamo, Upper Burmah, on Aug. 2nd, of intermittent fever, at the age of forty-one. He served in the campaign in the North-West Frontier of India in 1876, and was wounded in the chest; he was specially thanked by the Government of India for his services in a severe epidemic of cholera in Northern India. He was in charge of the 26th Field Company Royal Engineers in the Egyptian War of 1882 (medal and bronze star); and with the Nile Expedition in 1884-5 (clasp). Surgeon-Major Smith was recently in charge of the Station Hospitals at Bellary, South Station Hospital at Bangalore, Mandelay, and Bhamo. Before entering the service he had been house surgeon at St. Mary's, St. Peter's, and the Lock Hospitals in London, and had travelled widely.

H. E. B. FLANAGAN, M.R.C.S. ENG.,
SURGEON, ARMY MEDICAL SERVICE.

SURGEON HAROLD EDWARD BICKERSON FLANAGAN died on Aug. 8th, of typhoid fever, at the age of thirty-one, at Bangalore, Madras, where he had been doing duty at the South Station Hospital. Surgeon Flanagan was a man of very great ability. As a student at Guy's Hospital he achieved considerable distinction, obtaining the gold medal in medicine and various other prizes. In India, in addition to his high professional knowledge and character, he had already distinguished himself as a linguist, for in a few months he passed with ease the examination for the "high proficiency in Hindustani," and shortly afterwards the "higher standard in the Persian language." The Army Medical Staff loses in Surgeon H. E. B. Flanagan one of its most brilliant and promising members.

Medical News.

SUTTON SEWAGE SCHEME.—The Sutton Local Board has decided to purchase, at a cost of £1000, some additional land near the proposed site for the disposal of the sewage, when the scheme in contemplation is carried out.

FATAL FOOTBALL ACCIDENT.—A miner named Fox, of Carlton, twenty-six years of age, died on Sunday last from a fractured spine, sustained whilst playing in a football match between the Carlton Club and Hogg's Field United, Holbeck, on the previous afternoon.

LITERARY INTELLIGENCE.—Dr. Norman Kerr's work on "Inebriety" has been translated into Russian by Professor Kovalevsky of Kharkoff University, and published in Moscow. We understand that Mr. R. W. Partridge and Mr. E. Partridge, barristers-at-law, are about to publish an edited copy of the Lunacy Acts Amendment Act, 1889.

A SITE has been selected for a new station military hospital at Chester, near the Grosvenor-bridge, as part of the buildings connected with the headquarters of the new North-Western Military District. It is proposed to provide accommodation in the hospital for sixty patients.

MRS. MAYBRICK.—The Maybrick Committee have resolved to instruct counsel to apply to the vacation judge at next week's sitting for a writ of *habeas corpus*, on the ground that her sentence of penal servitude was illegal and *ultra vires*.

TRAPEZE ACCIDENT.—Another instance of the dangers attending acrobatic performances occurred at Pesth last week. While flying from one trapeze to another, a performer at Wulf's circus in the town missed his aim, and, falling outside the net, sustained serious injuries.

PRESENTATION.—A cheque for £100, together with a largely signed letter of regret at his approaching departure, has been presented to Dr. Edward Paget Thurstan, M.D. Univ. Camb., M.R.C.S. Eng., who is about to leave Southborough, Tunbridge Wells, and practise in the Canaries. Dr. Thurstan was a member of the local board, and took an active share in many philanthropic movements for the welfare of Southborough, where his presence will be greatly missed.

HUNTLY JUBILEE COTTAGE HOSPITAL.—On the 18th inst., a bazaar in aid of the endowment of the Jubilee Hospital at Huntly was opened in the Public Hall there, in presence of a large number of ladies and gentlemen, by the Duke of Richmond and Gordon. On the following day Dr. Farquharson, M.P., was present, and remarked on the gratifying success which had attended the previous day's proceedings and the excellent arrangements which had been made in the building for the welfare of the future inmates.

ENTERIC FEVER IN WELLINGTON, N.Z. — Mail advices state that enteric fever prevailed at Wellington, New Zealand, during the latter end of July, and the sanitary condition of the town was most unsatisfactory. Mr. Fulton, engineer for the Manawater Railway Company, had succumbed to the epidemic, whilst Captain Savill, aide-de-camp to the Governor, had been in a critical condition, but, according to the latest accounts, was improving. The Countess of Onslow and her children had left Wellington for Nelson, presumably to avoid unnecessary risk.

POISONOUS BERRIES.—On Sunday last three young married men, residents of Kilburn, went for a walk, during which they gathered a quantity of berries, which were taken to their respective homes, made into pies, and eaten. As a result, the members of the three families, numbering nine in all, were taken in the afternoon to St. Mary's Hospital, Paddington, suffering from poisoning. One of the young men soon rallied to treatment, but the remainder were, according to last accounts, still in a serious condition. The berries were of that variety commonly known as "deadly nightshade."

TUBERCULOUS DISEASE AND THE SHEFFIELD BUTCHERS.—On Tuesday a numerous meeting of butchers, attended by deputations from several towns, was held at Sheffield, in consequence of the medical officer of health, instigated by the prosecutions at Glasgow and other places, having condemned the carcase of a young beast which had suffered from tuberculosis. The question is, no doubt, of importance to the trade generally. The butchers contend that, in its primary stage, the disease does not render meat unfit for human food; whilst medical opinion asserts that meat affected by the disease at any period is unwholesome and not fit for consumption.

REPORTED DEATH UNDER CHLOROFORM. — The death is announced of Mrs. Neale, aged twenty-four, residing at Handsworth, Staffordshire, under painfully sudden circumstances. Mrs. Neale had decided to have several teeth extracted, and the family medical attendant, together with a local dentist, were called in. Chloroform was administered, but before she had drawn her breath half a dozen times she suddenly slipped from the chair and expired almost immediately. It is thought that death resulted from syncope brought on by excitement. The professional gentlemen engaged are stated to have taken every precaution in the administration of the anæsthetic.

Digitized by Google

AN INSANITARY DWELLING.—At a meeting, last Thursday, of the Vestry of St. James's, Westminster, it was reported that inquiries had been made with respect to the recent death in Berwick-street, when comments were made on overcrowding and insanitary dwellings. The case was that of a coach-painter named Ebers, who lived in a small back kitchen amid the most filthy surroundings. Dr. Jackson of Poland-street described the place as entirely unfit for habitation, and said it ought never to have been inhabited. The Sanitary Committee reported that there was no reason to take action as to the filthy state of the premises, as it was caused by the condition of the occupants.

BEQUESTS AND DONATIONS TO HOSPITALS.—The treasurer of the British Home for Incurables has recently received £20 as a donation from an anonymous friend resident in Somerset, Cape Colony.—The Duke of Portland has intimated his intention to make a donation of £50 towards the funds of the Doncaster Infirmary.—The late Miss Jane Winlaw, of 17, Queen's-road, Aberdeen, has left by her will the following legacies—viz., £2000 to the Royal Infirmary, Aberdeen; £2000 to the Incurable Hospital, Aberdeen; and £500 to the Sick Children's Hospital, Aberdeen.—Mr. John Beaumont, late of Ravensknowle, Dalton, has bequeathed £2000 to the Huddersfield Infirmary.—The net result of a concert held at Southgate on the 17th inst., in aid of the cottage hospital, amounted to upwards of £40.

HEALTH OF THE CITY OF LONDON.—Dr. Sedgwick Saunders, the medical officer of health for the City, reported to the City Commission of Sewers, at their meeting on Tuesday, that in his experience there had never been a summer when the city had been healthier or complaints fewer. The average death-rate was at the rate of 9·24 per 1000 per annum of the population; 741 houses had been inspected, of which eighteen required sanitary improvement. Thirty-three tons of meat had been seized and destroyed as unfit for human food. Serious defects were found to exist in the vaults beneath several of the City churches, and remedial measures were being proceeded with to abolish these insanitary conditions. At the mortuary, sixty-five articles of clothing had been disinfected and fifteen bodies received. There were registered in the City in the past seven weeks sixty-four deaths and ninety-five births.

MANCHESTER ROYAL INFIRMARY.—At the annual meeting of the board of the Manchester Royal Infirmary, Dispensary, and Lunatic Hospital or Asylum, the report, which was adopted, stated that during the twelve months ending 24th June last, 43,985 persons had received assistance at the Royal Infirmary and its allied institutions at Cheadle and Monsall, 36,143 being treated as out- and home-patients, against 33,288 last year. The total income for the year was £22,331 (a reduction compared with the previous year of £1203), and the total expenditure £21,514. The report adds that the "board do not regard with satisfaction the circumstance that so considerable a proportion of the working class of Manchester and the neighbourhood are in the receipt of charitable medical relief. They are of opinion that it will soon be desirable to take such steps as circumstances render necessary to require these patients to contribute much more largely than they have hitherto done to the funds of the institution."

GLASGOW AND OVERCROWDING.—Dr. James Burn Russell, medical officer of health for Glasgow, in his evidence before the Select Committee on Sweating, explained a system of ticketing and inspecting of small houses which had been in existence in Glasgow since 1862. Houses containing not more than three apartments and not more in the aggregate than 2000 cubic feet are measured, and have affixed to them on the outside door a tin-plate ticket on which the cubic contents are marked, and the number of inmates allowed in consequence. These plates are a guide to the night inspectors, who compare the number of inmates they find with the number the house ought to have, and a violation of the bye-law involves a summons before the magistrate. The system works very smoothly, and the authorities are satisfied that it is a great preventive of overcrowding. About 24,000 houses are on the register. The authorities intend asking for legislative powers to increase the allowance of 300 cubic feet of space per adult to 400 feet.

MISSION TO DEEP-SEA FISHERMEN.—Dr. W. T. Grenfell delivered a lecture in the Albert Hall, Leeds, last week in aid of the Mission to Deep-sea Fishermen. An interesting portion of the lecture was that which described the rough-and-ready means formerly used in bringing an injured fisherman to land, and the improved methods now adopted. Formerly a fisherman often bled to death because no means of aid were at hand, but now there were hospital ships, and all the fishing boats were fitted with proper temporary appliances for accident cases. The lecture, which was illustrated by dissolving views, concluded with a collection from the large audience in aid of the mission funds.

PROVINCIAL SUNDAY AND SATURDAY HOSPITAL COLLECTIONS.—The Henley Hospital Sunday collection, on the 15th inst., realised £26 2*s.* 2*d.*—The Friendly Societies' Church Parade, at Barnet, on the 15th inst., produced, after paying the expenses, £15 10*s.*, which has been divided between the Barnet Cottage Hospital and the Herts Convalescent Home.—The receipts of the recent sports of the North London Police and Tradesmen at Tufnell Park, in aid of the funds of the Great Northern Hospital, amounted to £50, which has been paid over to that institution.—The Committee of the Loyal Order of Ancient Shepherds, Bristol, has forwarded to the Royal Infirmary £23, and a like amount to the General Hospital, the Children's Hospital, and the Eye Hospital, Bristol.—The Hospital Sunday Collection at Ware, Herts, in aid jointly of the Hertford Infirmary and Herts Convalescent Home, produced nett about £60.—The Hospital Saturday Collection at Salisbury on the 21st inst. amounted to £58 2*s.* 11*d.*—The Hospital Sunday collection at Falmouth on the 22nd inst., in aid of the Cornwall Infirmary and Falmouth Dispensary, amounted to a little over £22.

CLAYTON HOSPITAL (AND WAKEFIELD GENERAL DISPENSARY).—The 102nd report of this institution, which was founded by Thomas Clayton in 1854, and incorporated with the Wakefield General Dispensary, established in 1887, was adopted at the annual meeting held last July. The report showed no particularly striking feature worthy of remark, the work during the past year having gone on steadily in much the usual manner. There had been an increase in the number of in-patients compared with the previous year, and the daily average number of beds occupied was thirty-one. Of out-patients the average number of cases per week was 877 against 677 in the preceding year. In making an urgent appeal for funds, the committee desire to remind benefactors and subscribers that "dispensary recommendations" are intended for the assistance of people whose weekly earnings are insufficient to meet the additional expenses incurred in times of sickness, and that to give these tickets to persons who are able to pay for advice not only has a pauperising effect upon the recipients, but is a positive injury to those very doctors to whom the institution is so greatly indebted.

COTTAGE HOSPITAL FOR MEXBOROUGH. — The efforts which have been made for some time past to establish a Cottage Hospital for Mexborough have at last met with success, and, owing to the munificence of Mr. A. Montagu, the working men of the district will soon possess an institution fitted up with every requisite. As a mark of gratitude, it has been decided to call the hospital "The Montagu Cottage Hospital." At a meeting of the Committee of the Hospital the following rule applicable to the medical staff was read and approved:—"Every duly qualified and registered medical man within a radius of three miles shall have the right to attend patients in the hospital upon the request of the patient, or his friends, conveyed through the nurse; but no patient, having chosen his medical attendant, shall have the right to change him during his stay in the hospital without the consent of the medical staff. A consultation of the medical staff may be called in serious cases, and shall be called before a major operation. In the absence of any request for a special medical attendant, the patient's ordinary club or private doctor shall be the one consulted. The medical staff shall consist of such duly qualified medical practitioners residing within a radius of three miles of the hospital as will, upon invitation of the Committee, allow their names to be printed in the rules of the institution, and their titles shall be 'surgeons to the Montagu Cottage Hospital;' such staff shall have the power to settle the provisional questions with regard to the carrying on of the work."

A GIFT TO GLOSSOP.—Mr. John Wood, of Whitfield House, desirous that the ratepayers should not be called upon to provide the additional amount required to complete Wood's Hospital, which his late uncle founded, has forwarded to the Town Council of Glossop, as a gift, a cheque for £1000, which more than covers the sum required. The late Mr. Daniel Wood, in the Jubilee Year, gave £6000 for the purpose of building the hospital, and £19,000 for its endowment.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

CAMPBELL, H. J., L.R.C.P. Lond., M.R.C.S., has been appointed Demonstrator of Biology, Guy's Hospital.

CRISP, J., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon and Secretary to the Stamford, Rutland, and General Infirmary.

HEWLETT, C. W., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Coventry Hospital.

HUNT, ROBERT, M.R.C.S., L.R.C.P.Lond., has been appointed Honorary Surgeon to the Blackburn and East Lancashire Infirmary, vice Dr. Stephenson, deceased.

JOHNSON, FRANCIS, M.R.C.S., has been appointed Medical Officer of the Beaconsfield District, Amersham Union.

JOHNSON, R. S., L.R.C.P., L.R.C.S. Edin., has been appointed Second Assistant Medical Officer to the St. Marylebone Infirmary, vice L. Hickey, M.R.C.S., L.S.A., M.B. Dur., resigned.

JONES, RICHARD L., L.M.K. & Q.C.P., R.C.S.Irel., has been appointed Government Physician for the District of Hanalei, Kauai, Sandwich Islands, vice Sidney E. Craddock, M.R.C.S., L.R.C.P.Lond., deceased.

MATTHEW, C. P., L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Medical Officer No. 5 District, Southmolton Union, vice Sanders, deceased.

MOULLIN, C. W. M., M.D., F.R.C.S. Eng., has been appointed Surgeon to the London Hospital, vice Couper.

MILLER, HUGH, M.D., has been appointed Public Vaccinator of the District of Birkenhead, in the Birkenhead Union, vice P. M. Braidwood, M.D., resigned.

O'REILLY, GEORGE HARTLEY, M.B. Lond., M.R.C.S., L.S.A., has been appointed House Surgeon to the Cancer Hospital, Brompton, vice C. E. Valpy, B.A., M.R.C.S., resigned.

PAPILLION, JAS. W., M.R.C.S., L.S.A., has been appointed Medical Officer of Brent Knoll District, Axbridge Union.

REARDON, D. F. B., L.R.C.S. Irel., L.K.Q.C.P. Irel., L.M., has been appointed Medical Officer of the Bruff Dispensary District, Kilmallock Union, vice MacNamara, resigned.

ROBERTSON, CHARLES, M.B. & C.M.Edin., has been appointed House Surgeon to the Birmingham New Workhouse Infirmary.

SIMS, G. S., L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Surgeon to the Derby Borough Police.

STARLING, E. H., L.R.C.P. Lond., M.R.C.S., has been appointed Demonstrator of Physiology, Guy's Hospital.

THOMAS, DAVID E., M.R.C.S., L.S.A., has been appointed Medical Officer of the Stradbroke District, Hoxne Union.

THORBURN, J. D., M.B. Toronto, L.R.C.P. Edin., has been appointed Resident Medical Officer to the Manchester Hospital for Consumption, vice Dr. Burnett, resigned.

TUBBY, A. H., F.R.C.S., L.R.C.P. Lond., has been appointed Demonstrator of Physiology, Guy's Hospital.

WHITELEY, D. F., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Wallasey Dispensary, vice F. H. Potts, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

GATESHEAD DISPENSARY.—Resident House Surgeon. Salary £200 per annum, with furnished apartments in the dispensary, coals and gas.

GENERAL DISPENSARY AND INFIRMARY, Jersey.—Resident Medical Officer. Salary £120 a year, with furnished apartments and attendance.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physicians.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Resident Medical Officer. Salary £50 a year, with board and lodging.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—House Surgeon for six months. Salary £50 per annum, with board and residence.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Junior House Surgeon. Salary £50 per annum, with board and apartments.

SOUTH DEVON AND CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary £100, with board and rations.

UNIVERSITY COLLEGE, Dundee.—Professor of Physiology. Salary £350 per annum, with two-thirds of the fees.

UNIVERSITY OF SYDNEY, New South Wales.—Applications to Agent-General for New South Wales, 9, Victoria-street, S.W.:—1. Challis Chair of Anatomy. 2. Challis Chair of Law. 3. Challis Chair of History. 4. Challis Chair of Logic and Mental Philosophy.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Dental Surgeon.—Also Honorary Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

FENNELL.—On Sept. 17th, at Trumpington, Cambridge, the wife of Dr. C. A. M. Fennell, of a daughter.

HUNT.—On Sept. 19th, at Clydesdale Villa, Sheffield, the wife of Lewis Gibson Hunt, M.D., of a daughter.

MAC DOWEL.—On Sept. 17th, at Edenfel, Omagh, the wife of E. C. Mac Dowel, M.D., of Sligo, of a daughter.

MARTIN.—On Sept. 20th, at Brunswick-street, Sheffield, the wife of Dr. John W. Martin, of a daughter.

PESKETT.—On Sept. 20th, at Oakover, Burnham, Somerset, the wife of A. W. Chalmers Peskett, M.A., M.B., B.C. Cantab., of a daughter.

RENDALL.—On Sept. 8th, at Aix-les-Bains, the wife of Stanley M. Rendall, M.D., of a son.

RINGER.—On Sept. 18th, at Lower Seymour-street, Portman-square, the wife of Deputy Surgeon-General Theobald Ringer, late Bengal Army, of a daughter.

SCHLICH.—On Sept. 17th, at Coopers-hill, the wife of Dr. W. Schlich, of a daughter.

TOLLER.—On Sept. 20th, at Castle House, Ilfracombe, the wife of Charles W. E. Toller, Esq., of a daughter.

WEBB.—On Sept. 20th, at Kingsbridge, South Devon, the wife of W. H. Webb, M.R.C.S., L.R.C.P. Lond., of a son.

MARRIAGES.

DICKMAN—BARNES.—On Sept. 19th, at the Parish Church, Eye, Henry Dickman, M.B., Buntingford, Herts, to Edith Julia, elder daughter of Henry J. Barnes, Esq., J.P., Eye, Suffolk.

EVE—COX.—On Sept. 19th, at St. Mary's, Harrow-on-the-Hill, by the Rev. F. Hayward Joyce, Vicar, and the Rev. T. Smith, Frederic S. Eve, F.R.C.S., of 125, Harley-street, Cavendish-square, to Caroline Ella, only daughter of Herbert E. Cox, of Ashleigh, Harrow. No cards.

MACKENZIE—LOFTS.—On Sept. 11th, at the Presbyterian Church, Kimberley, South Africa, John Eddie Mackenzie, M.B., C.M., to Ethel Marian, second daughter of Frederic F. Lofts, Maude-road, Camberwell, S.E.

MCLEAN—LAWSON.—On Sept. 25th, at All Saints' Church, Fulham, by the Rev. W. Goodwin Kerr, M.A., William W. L. McLean, M.R.C.S.Eng., L.R.C.P. Lond., younger son of J. W. McLean, Esq., of Fulham Park Gardens, S.W., to Minnie, youngest daughter of John Lawson, Esq., of Italian Villa, Hurlingham-lane, S.W.

NEILSON—TULLIS.—On Sept. 19th, at Blackfriars Parish Church, Dennistoun, Glasgow, by the Rev. Thomas Somerville, M.A., assisted by the Rev. Albert Goodrich, D.D., Henry J. Neilson, M.D., Rulwell, Nottingham, to Annie Keil, eldest daughter of John Tullis, Esq., Inchcape, Dennistoun, Glasgow.

PRATT—MOXON.—On Sept. 19th, at St. Giles' Church, Northampton, by the Rev. R. A. White, M.A., W. Sutton Pratt, L.R.C.P. Lond., M.R.C.S., of Weedon, Northants, to Eleanor Mary, second daughter of William Moxon, M.R.C.S., &c., of Northampton.

STOKES—HILLER.—On Sept. 25th, at St. Margaret's, Whalley Range, Manchester, by the Rev. D. Dorrity, John Stokes, M.B., B.S., M.R.C.S., L.S.Sc., Parkgate, Rotherham, to Margaret Amy Hiller, only daughter of Henry Hiller, Stanley-road, Manchester. No cards.

DEATH.

RICHARDSON.—On Sept. 19th, after much suffering, at Camden-road, London, the residence of his sister, Charles Schofield Richardson, M.D., M.R.C.S., of Dursley, Gloucestershire, aged 61.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

ATTITUDE OF DROWNED PERSONS.

Mr. Ellis Lever.—The quotation is not free from "philosophic doubt." It is quite consistent with what we know of the spinal reflex actions when the inhibitory influence of the brain is abrogated—e.g., if you put a male and female frog into water impregnated with strychnia, the former exhibits the attitude of embrace, whilst the latter assumes the more passive state of limb extension. Probably these physiological forces as they die out with the death of the animal leave full play to purely physical forces; and in the case of drowning we should expect in most cases, whichever the sex, that the face would be found uppermost, the buoyant action of the gas in the intestines determining this position. We are, of course, assuming that it is a case of drowning in deep water.

TÆNIA.

To the Editors of THE LANCET.

SIRS,—A young lady, a patient of mine, has during the last six months been troubled with tapeworm (tænia mediocanellata). A year previously her life was for a time made utterly miserable by the presence of thread worms; these, under treatment, were effectually removed, but only to be replaced by the larger worm. The treatment adopted for the latter was two or three days' careful dieting, aperients, and a dose of male fern. Result: the passage of the worm. On three occasions this treatment has been carried out, and in each instance with a like result, and the passage of the head. Between the expulsion of the worm and its reappearance, which in each case has been exactly ten weeks, the greatest possible care has been exercised in avoiding improperly cooked meat.

I should be very much obliged if any of your numerous readers could suggest any treatment likely to prevent the recurrence of this troublesome parasite. I am, Sirs, yours truly,

Sept. 24th, 1889. H. C. S.

TETANUS IN PUERPERY.

To the Editors of THE LANCET.

SIRS,—I observe in THE LANCET of Aug. 17th and Sept. 21st that Mr. Henry Peacock and Mr. Johnson Herbert remark that puerperal tetanus is not described in any obstetric work. Allow me to point out that the subject is fairly treated of in the System of Obstetric Surgery and Medicine by myself and Dr. Fancourt Barnes (see vol. i., p. 376, and vol. ii., p. 381). I am, Sirs, yours faithfully,

Harley-st., Sept. 23rd. ROBERT BARNES.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—I notice in your Students' Number you recommend as one of the text-books on the Diseases of Children the work of Ashby and Jones. Permit me to correct this, and say that the book is by Ashby and Wright.

I am, Sirs, yours obediently,

Manchester, Sept. 25th, 1889. G. A. WRIGHT.

VACCINATION MEMORANDA.

A CORRESPONDENT having pointed out that the figures we gave in our last issue as to vaccination and small-pox on board the *Preussen* did not account for all the 312 persons referred to, we would add that in addition to the cases quoted there were sixteen persons on whom vaccination was alleged to have been performed, but who showed no evidence whatever of the operation. Whether these should be placed among the vaccinated or the unvaccinated it is impossible to decide. Two were attacked, and both recovered; but one, a girl, was twice vaccinated during the incubation period of her small-pox. The remaining thirteen do not, we find, happen to be referred to for the purposes of the paper under consideration; but a former paper by Dr. Ashburton Thompson shows them to have been persons who had previously had small-pox. Three of them suffered a second time from the disease, but they all recovered.

A. Neville.—We do not prescribe.

ATTENDANCE ON MEDICAL MEN AND THEIR FAMILIES.

To the Editors of THE LANCET.

SIRS,—Might I ask you to give me the benefit of your advice on the subject of attendance on medical men and their families?

The town in which I live is noted for its schools and educational establishments of all kinds. Not a year passes but I am called upon to attend some medical *confrère* who has retired from practice and the members of his family, or the children of men in active practice, pupils at one or other of the schools. Hitherto I have made it a rule not to charge in such cases. A few examples will serve to show you what my experience so far has been. I attended Dr. A. and his daughter on several occasions; in fact, during the whole of their stay here. Dr. A. left without calling or even writing to thank me. Surgeon B. consulted me for a very obscure affection, and was benefited by my treatment. He went up to London to see a celebrity, and I have never heard from him from that day to this, though he had promised most faithfully to let me know the great man's opinion. Dr. C., a well-known consultant, and now a member of one of our governing medical bodies, sent his two daughters to a school here which I attend. Both were very delicate girls, and were taken ill soon after their arrival. In the space of six months I was obliged to make no fewer than sixty-three special visits for these young ladies, and to keep up a long correspondence about them with their father. Dr. C., as a token of his gratitude, sent me a volume of his lectures, market price 5*s.*, and a formal letter of thanks. These are typical, but unfortunately not exceptional, cases, and others of my friends tell the same tale. I should like to know whether I should be justified in pursuing a different course for the future. A word of advice from you on the subject would oblige, Yours very truly,

Sept. 20th, 1889. AN OLD SUBSCRIBER.

*** The best service we can render in this matter is to publish letters such as the above, which set forth "the other side" of this question. It is impossible to maintain that a medical man has a right to claim the services of another medical man at all times and at much inconvenience without consideration and without gratitude. We can advocate nothing that would mar or lessen the feeling that one medical man has in favour of assisting another in any circumstances of illness. But this feeling must not be abused; yet it is easy to see that in such circumstances as our correspondent describes it is apt to be and actually is abused. In a city famed for its educational institutions great labour and hardship may be imposed on a medical man by the thoughtless use of this kindly rule, which was never meant to be indiscriminately applied in such cases.—ED. L.

THE BENTLEY PRIZE AT ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Would you be good enough to correct a mistake which appeared in your issue of Sept. 14th?

The Bentley Prize at St. Bartholomew's Hospital this year was not won by Messrs. F. W. Andrewes and E. A. Edelsten, who were last year's prizemen, but by Messrs. R. H. Elliot and R. F. Standage.

I am, Sirs, yours sincerely,

St. Bartholomew's Hospital, Sept. 25th, 1889. HENRY T. BUTLIN.

Cousin (Lincoln).—When cousins are healthy, and have no proclivity to disease, they may safely marry, but the existence of strongly marked scrofulous or other taint should be regarded as a bar to such marriages. Huth's book might be consulted on the subject of Consanguineous Marriages.

HYDROPHOBIA.

To the Editors of THE LANCET.

SIRS,—Could any of your numerous readers inform me as to the number of cases of hydrophobia treated in the larger hospitals of London during the past year? I am too old and infirm to make the inquiry myself. I was more or less connected with St. George's Hospital from the year 1825 to the year 1870, and I saw but two cases of the disease. Of course, some may have escaped my notice.

I am, Sirs, yours truly,

Buntingford, Herts, Sept. 13th, 1889. T. E. HICKS, F.R.C.S.

FELDSHERS.

IN rural districts in Russia, where the population is very scattered and towns are a long distance apart, it is impossible to obtain medical aid except on rare occasions, and after a long delay. Provision is, however, made for attendance in minor cases and for what might be called "first-aid" in serious ones by the distribution of partially educated men, denominated *feldshers*, or *feldscheers*, in the villages. The feldsher acts under the orders of the doctor who has charge of the district, and in serious cases summons his principal. The feldsher is a man who has had some training, usually in a special training school and in military hospitals, as a kind of hospital sergeant. He is now obliged to have a very fair general education, as he is not admitted to the feldsher school until he has gone through the four lower forms of a gymnasium or has passed an examination which is probably as difficult as the Arts examination of Apothecaries' Hall or the junior certificate examination of the Oxford and Cambridge Schools Examination Board. Both Latin and Greek were required until recently, but the Minister of the Interior has now issued a notice stating that Greek will no longer be required.

DR. WARD COUSINS' ANTISEPTIC ARTIFICIAL TYMPANUM.

To the Editors of THE LANCET.

SIRS,—I am very pleased to see, from your issue of the 14th inst., that Dr. J. Ward Cousins has brought his new antiseptic artificial tympanic membrane to the notice of the profession. From personal experience of over twelve months, I can frankly state that it fulfils all the qualities claimed for it and even more. For many years I have had a perforation of the right tympanic membrane, but no discharge during the past five years. I consulted several eminent aural surgeons, and used different kinds of artificial drums, but none of them improved my hearing, so that I was, to say the least, somewhat sceptical as to deriving any benefit. However, my doubts were soon dispelled on using one of the drums invented by Dr. Ward Cousins, for I could hear well, and have continued, by the use of the drums, to do so since. Only those who have been afflicted with deafness (even on one side) can appreciate the blessing of restored hearing. I have not experienced the slightest inconvenience from the presence of the artificial drum in my ear; in fact, I much prefer to have it there. Owing to the success and comfort in my own case, I have supplied them to several of my patients, and in all with marked improvement in their hearing. I will only mention two cases, which will, I think, be sufficient to convince anyone that in this new antiseptic tympanic membrane we have a very valuable invention.

J. L——, aged forty-four, a shipwright; very deaf in both ears; perforation of both tympanic membranes of twenty years' duration; no discharge. A drum was placed in each ear about six months ago; since then he has continued to use them and can hear quite well. He changes them twice a week.

The other is a still more remarkable case. E. A——, aged sixty-six years, widow, had used an ear-trumpet for several years, but from the time she commenced to use the artificial drums until her death she was able to hear well, and discarded the ear-trumpet.

I find that patients can easily change the drums by the use of the little instrument which Dr. Cousins has invented for the purpose.

I am, Sirs, yours obediently,

Portsmouth. RICHARD EMMETT.

PROFESSIONAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—May I ask you to kindly give your opinion on the following:—

1. A general practitioner, without the permission of anyone, but at the instance of a friend of the patient, visits, examines, and gives an opinion upon a case which he is told at the time to be under treatment and to have been seen by a specialist, and who neither then asked permission of the relatives or doctor in attendance, nor sent any word of his intention.

2. A hospital surgeon and teacher commences practice in the country by elaborate newspaper announcements and by the issue broadcast of a copy of testimonials in the form of a small pamphlet, and the re-issue of these to any new arrivals in the neighbourhood.

I am, Sirs, yours truly,

September, 1889. A LEARNER.

*** The publication of such instances of unprofessional methods is one of the best ways of treating them. They may serve as a beacon to deter others from such violation of medical ethics. They would be a proper subject of protest by the medical men of the neighbourhood.—ED. L.

MEDICAL FEES IN LIFE ASSURANCE.

To the Editors of THE LANCET.

SIRS,—I recently examined a life for The —— Insurance Society, and received in return for my opinion the sum of 10*s.* 6*d.* instead of £1 1*s.*, because the policy was for a sum under £500. Surely this was hardly to be expected when dealing with an office of long-standing and of great financial stability. Will any of your readers tell me whether it is a usual proceeding?—I am, Sirs, yours faithfully,

Sept. 18th, 1889. G. F. H.

*** The question is referred to in another column.—ED. L.

PRINCIPALS AND ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—I see in your issue of this week what appears to me rather a remarkable opinion on "the respective claims of principals and assistants to fees"—viz., that the division of the fee in a court case was right. The assistant is generally engaged to give the principal assistance in all branches of his profession, for which he receives a salary. Surely he has no right to do work for payment and use his energies apart from the practice, as his whole time is paid for. It appears to me that the principal is entitled to *all* fees, and if the assistant were even to write an article for a journal for which he received payment, that sum would be morally the principal's, as the energy which was expended on it was energy paid for by the principal to be expended on the practice. Of course, if the assistant asked for and obtained leave the case would be different. In midwifery cases the assistant, by arrangement, sometimes gets part of the fee. By arrangement, it might become his due in jurisprudence cases. I am, Sirs, yours truly,

Sept. 21st, 1889. PRINCIPAL.

*** We agree with our correspondent, though he carries his argument rather too far when he maintains that a principal is entitled to the fee for a literary article written by an assistant, presumably in spare moments and without neglecting the interests of his principal. We said last week, and in reference to the particular case, that the assistant must be considered as acting for the principal. The division of a fee by the principal is, in the absence of contract, generous. When we said that the division of this particular fee was right we did not mean to imply that the principal was bound so to divide it, but that as an irregular and unexpected sort of fee it was well to divide it. A principal loses nothing by a little liberality in such circumstances.—ED. L.

A. B.—We cannot regard as professional conduct such as that described. We think that remonstrance should be offered; and if this be unavailing, a severance of professional relations should be effected.

THE REGISTRATION OF MIDWIVES.

To the Editors of THE LANCET.

SIRS,—We are glad to see that public attention is at length being called to the crying evil of uncertificated women practising as midwives. The recent cases, reported in various papers, of death through puerperal fever, conveyed to six poor lying-in women by an uncertificated midwife, set forth in a striking manner the need of legislation as to the employment of untrained and irresponsible women. Though there are now many well-trained and certificated midwives in practice, the uncertificated woman will continue to be employed to the great detriment of mothers and infants, and nothing but compulsory registration—that is, by Act of Parliament—will meet the case. It is earnestly hoped, therefore, that the Bill for the Registration of Midwives, notice of which has been given in the House of Commons, will shortly extend to the mothers of England that protection in childbirth which they can command in every other European country. The Midwives' Institute has been quietly and steadily working towards this end for the last eight years, and will gladly supply all information on this subject to anyone desiring it.—I am, Sirs, yours faithfully,

MARGARET NICHOL,

15, Buckingham-st., Strand, W.C. Secretary, Midwives' Institute.

COMBINATION OF ANTIPYRIN AND SALICYLATE OF SODA.

To the Editors of THE LANCET.

SIRS,—During last week I was called upon to visit a patient who was suffering from a rheumatic sore throat and severe pains in the legs, which afterwards proved to be antecedent to an attack of erythema nodosum. To allay the pain I ordered powders containing antipyrin and salicylate of soda. To my astonishment, I found that by the combination of these two drugs a cream resulted after a period of a few hours. Evidently a hygroscopic compound resulted which attracted moisture from the air. A similar cream or syrup is produced by the combination of chloral and camphor, and also by the union of alumen and sulphate of zinc. Does the syrup that is formed result in the formation of a new compound? And, if so, what is its nature and formula? Further, is the pharmacological action of the two drugs destroyed by the combination? Since I discovered the effect of the union of the two drugs I now order them in solution. Later I tried to mix antifebrin and salicylate of soda (both white powders), and I found that a pink powder resulted. What is the change in this case?

I am, Sirs, yours obediently,

Burnley. JAMES MONTEITH, M.B., M.Ch.Edin.

Medical Diary for the ensuing Week.

Monday, September 30.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; and Thursday, 9 A.M.

Tuesday, October 1.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.
SOCIETY FOR THE STUDY OF INEBRIETY.—4 P.M. Mr. H. Ernest Trestrail: Some of the Circumstances which Favour the Development of Inebriety, and how to meet them.—The President (Dr. Norman Kerr): Note on "Is there an Arsenic Inebriety?"

Wednesday, October 2.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.
OBSTETRICAL SOCIETY OF LONDON (the Society's Library, 54, Berners-street, W.).—8 P.M. Specimens will be shown. Dr. Herman: (1) A Contribution to the Anatomy of the Pelvic Floor; (2) On the Changes in the Pelvic Floor which accompany the Slighter Degrees of Prolapse.

Thursday, October 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, October 4.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, October 5.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

Introductory Lecture
ON
HIGHER MEDICAL EDUCATION.

Delivered at St. George's Hospital at the opening of the Medical Session, 1889-90.

BY T. CLIFFORD ALLBUTT, M.D., F.R.S.,
COMMISSIONER IN LUNACY.

GENTLEMEN,—The delivery of an address on the anniversary of a school of medicine is an old custom, and one honoured by distinguished men, yet neither age nor distinction has protected it from some adversity of modern criticism. With this royal water the spirit of our time assays all things, great and small, lowly and exalted, and by this test accepts, changes, or rejects them. I believe, however, that a true economy will approve these addresses and use them still. A bare contract may answer the wit, but will not fill the hearts of men, nor kindle the fire of young disciples. To hundreds of young men to-day is a great day, not only because on this day they enter upon a new calling, but even more also because to-day is to them the first day of freedom. How vividly I remember—nay, how keenly I still feel—the emotion of that day in my own life—the day when I first entered my own sitting-room, sat beside my own table, and took my life into my own hands! I took up my life, as now you take up each of you your own, with a joy beyond words and laughter — that joy in the possession of my own faculties, for better or for worse, which is the birthright of certain races of men. We know not then the burden of life, so easily we carry it—so easily that for the first few years we are apt to knock it about a good deal and even to make some lasting dints and scars upon it, not always in very honourable conflict. Still, with all that, the freedom of the city within ourselves is a priceless boon, and one which no brave man would give away, whatever the burdens and hardships that freedom brings with it. Indeed, to take our freedom in both our hands, and to step forth into vacancy therewith, would be a cruel irony; we should be as one that beateth the air. There are adventures before us, work to break our strength upon, olive and wild parsley to win, great captains to follow, and a mistress to worship. Your mistress, gentlemen, is the Art of Medicine, and your freedom is her service. *Studia libertate proveniunt.* You will not begin work with gestures and vociferations, but, as English boys begin a great cricket match, with a seriousness, even a solemnity, of bearing consistent with the deepest intensity of purpose and the hope of standing side by side with the best of us. All men conscious of strength are calm enough to wait till they know where to use it, and will bide their time. The best soldier best loves discipline, and looks most loyally to his commander. He knows his powers are too good to waste, and the stronger he is the deeper his devotion. Those of us who are growing old, whose fires burn lower, whose limbs are laggard, involve ourselves in our wisdom and try to avert our envious eyes from your precious gift of youth. I try sometimes to comfort myself in my age by remembrance of my tingling resentments when, in the former years of my practice—and they seem but as yesterday—I was politely postponed as too young for confidences. My dear young friends, we who pride ourselves on the price of experience, on our sagacity, the gift of time, would give them all twice over for your boon of youth. Some day, when it is gone, you will wistfully look back upon it; but when a man looks back his Eurydice is gone! And what of all qualities of youth is the most precious? That which we older men try to breathe again from you, try to rekindle by the light which is upon your young faces—the quality of enthusiasm. To-day I, unworthy, am to many of you the first teacher of medicine, and the first words you hear in the porch shall be these: Work with us and keep us young. If you keep us young, we shall not destroy the spontaneity of your life; we shall not limit the range of your outlook by the bounds of our dogmatisms. You shall keep our minds flexible, and we will temper your energies. Above all things, know that we call you not here to run your minds into our moulds. We call you here on an excursion—on an adventure—on a voyage of discovery into space as yet uncharted. We have passed before you through the gate of Hercules; we have touched sometimes on the happy islands; we, like the great Ulysses, shall lead you through our experience, "whither gleams beyond an untravelled world." Every hour shall save "from that eternal silence something more, a bringer of new things." Would it be well, then, when we see you upon the threshold of our house, that we should not step forth and give you welcome; that we should leave you to file silently into dusty lecture-rooms, and to stand in tail to inscribe your names on the roll? That would be as dreary a setting forth as a marriage at a registry office; and, if I have but a boxwood flute, I will pipe to you to-day.

Gentlemen, your eyes are to be fixed, not to-day only, upon men; now upon your teachers, who are to be men and not pumps. Those who would set aside all commemoration to-day would to-morrow set aside all courses of lectures. Why, in the name of goodness, say they, is the student to be brought to the lecture-room to hear words drawn from sources open to all; to fill laborious note-books with facts already printed in their manuals. If a lecturer is but a pump, doubtless you would do better to go to the springs for yourselves. But, surely, that which impressed us in our lecture-room days was far less the facts of our profession and far more the character and influence of the men who awakened and liberated our thoughts. I carried away, not rows of note-books—dead arid things—but an impregnation. At St. George's my lessons were the fire, the rapidity, the impatience of fallacy of Bence Jones; the deliberate sagacity of Fuller; the methodical learning and rectitude of Barclay; and in these I speak only of the dead. In Paris I admired the marvellous flexibility, acuteness, and urbanity of Trousseau, the heroic industry and penetration of Duchenne of Boulogne, the philosophic breadth of Bazin, and, if last not least, the great erudition of Daremberg, an erudition which his critical insight and catholic temper enabled him to wield so easily. He happily is yet spared to us, as are the teachers of Cambridge—my *alma mater*—as life-giving to me, but so near me that I cannot here speak of them as I would.

Your lecturers shall, in like manner, inspire you with fervour of spirit, shall teach you the way to handle our materials, the methods of our investigation of them, and the kind of ideas which we think will interpret them. Of finite knowledge we have nothing to fix in you, of finite mental form we have nothing, of systematic doctrine we should offer but a temporary scaffolding. You will not, indeed, have to go over all the ground that we have done. Our fathers saved us many a weary march in barren lands, and you will shorten the labours of your children. Knowledge, you remember, has no royal highways; she may be hidden beside the feet of the humblest wayfarer, and has revealed herself to him whose eyes are open when finer pilgrims have pressed haughtily on. In knowledge there is no great and no small; nay, rather accuracy in what you call small things is not only a virtue of method, but also of morals—an ethical and vital sense of the infinity of creation, and of the patient unsleeping instancy of things; on the other hand, what the world calls great things may be to the eye of wisdom as naught. Of this pride and this humility the lives which we live before you should be an example. Do not think that all this is vague declamation. If it be so, I fail indeed; for, to my mind, the idea of a university consists in a true conception of the force and value of personal teaching. How can an impersonal board be a university? A university is the collective soul of its dead and of its living teachers, an abiding inspiration, a *mater alma philosophiæ*. A university will teach you not to regard your studies within her gates as ends in themselves, but to regard them as progymnasmata or exercises; and if it cannot give a liberal education to every one of its sons, it can at any rate teach them all to know that there are such things as ideas, and to conceive the need of them. A university is a permanent embodiment of the ideal of wisdom as opposed to technical furniture—of the ideal of mental culture as opposed to the collection of "tips" and devices in the memory. Lectures, therefore, should not be comprehensive so much as stimulating, individual, and

Digitized by Google

even discursive. They should aim rather at the illumination of life than the direction of study, and cordial engagement to thought rather than to the exhibition and transference of acquirements. Fresh and novel perceptions may be welcome, even if precocious or unfounded, if also they are broadly conceived and keep the mind of the student alert:

> "..... The blossoms of Eternity lie hid
> In the dim kindling buds of dreams that keep
> A fluttering pulse within Time's broken sleep.
> Dreams are not idle, dreams have saved the world."[1]

Again, it is as much the duty of a lecturer to mark off the gaps and crudities in his knowledge as to set forth realised truth. If I seem in this way to be addressing myself more to teachers than to disciples, this is but a seeming, for my first purpose is to reveal to the newcomer of to-day that he comes, not as a subject, but as a junior fellow and colleague. The youngest of you can at any rate beat the bushes for us. *Multi pertransibunt et augebitur scientia.*

Dr. Pusey used to say that "Truth often depends more upon the character of him who enforces it than on its own"; and this, gentlemen, is true not only of your lecturers, but of yourselves. All of you will go forth soon, some of you are now going forth, to teach others, not, it may be, from such chairs as this, but each from his place in the world. What mental habit will you take with you, how will you practise, how will you teach? The humblest of you will have some teaching to do, formal or informal. It has so happened that few men have had the opportunities which I have had of forming judgments of our profession as a whole. On the one hand, in London and in the old Universities I have not ceased to associate with the leaders of medicine; and, on the other, I have in the north of England laboured incessantly with the rank and file. Among the leaders of our own, as of all other callings, we find men of great and varied endowments, who have each their own mastery and faculties too strong and individual to have owed very much to methods of education; but in the rank and file I must say that a certain lack of mental training and impenetrability to ideas too often make themselves seen. I am not now speaking of those practitioners who fulfil no more and have aimed at no more than common usefulness, but I speak of men who should be more than this.

On another occasion I have said, and to-day I repeat, that for personal virtues, for a certain ethical habit, which, in its loftiness, simplicity, and unselfishness, is perhaps incomparable, the general practitioners of medicine offer a noble example to all other men, for they carry their high standard of conduct with a humanity, a moderation, and a modesty which do not invariably adorn the righteousness of other men. Yet with all this breadth of practical ethics we do not generally find a corresponding breadth of mental culture. The master mind of Western civilisation has drawn a distinction between the τεχνικος and the φρόνιμος, between the man who is well equipped as a craftsman, trained to quick observation and ready dealing with the things of to-day, and the man who may or may not be so well skilled in practical matters, but whose knowledge is far wider and deeper; who has, in a word, a training in philosophy. The mere practical man, valuable as he is, has but a simulacrum of knowledge, a kind of sham or surface instruction, and, having no knowledge of principles, he tends to routine and is unprogressive and wasteful. He is a man of opinions, and as science undermines opinions and treats opinions with some irony and sarcasm, perhaps indeed with some injustice, the practical man tends to wince from science, and will even thank God that he is not a philosopher. His usefulness, then, great as it may happen to be, is essentially temporary and provisional.

It is far otherwise with the man whose mind is opened to ideas, who is, moreover, prepared for life not merely by the appropriation of the thoughts of others, but by the enlargement and development of his own intellect; for indeed we should not only become familiar with the laws of phenomena within our own pursuit, but also with the modes of thought of men engaged in other discussions and researches, and even with the laws of knowledge itself—that highest philosophy. Now this mental training, although it happily exists in a few, is not by any means the note of English medical practitioners as a class. This defect is to be referred to two causes—first, to the want of leisure and of contemplative life among them; and, secondly, to the lack of university education.

The duties of the family practitioner are all abroad. Unlike the lawyer, he has not to put his thoughts to the test of pen and paper; and so complete is his divorce from the desk that even his few spare hours are dissipated. In course of time, the ability even to write a letter becomes atrophied. Happily, however, there are compensations for us. Law and medicine both are liberal pursuits, and promote mental and ethical elevation, as opposed to trade, which, when untempered by the arts of invention, is an illiberal pursuit; and in these days of small profits and close industry, when commercial men can no longer find leisure for self-culture, may be, and often is, actually degrading. Indeed, medicine has an advantage over law in this, that it is more in contact with positive truths, while at the same time it is no less in contact with civil and moral phenomena. Hence the practice of medicine, as we see every day, tends especially to cultivate that kind of critical spirit which we call "common sense." Nevertheless, I repeat, the English doctor too often lacks reasoning power, breadth of view, and flexibility of mind. So, you may retort, does the common run of all men. But, gentlemen, on the whole, we have greater advantages in the kind of our calling, and should stand better. Moreover, I am setting no abstract ideal before you. You will observe that I have spoken of English practitioners—of those educated in England, but not at universities. Now, by English I mean not the Scotch, whether practising in England or at home. When called in consultation by a Scotchman, I expected to meet a man of philosophical mind; when by an Englishman, I expected to meet an honourable man, a shrewd man, a practical man, but not a man of philosophical mind. Now, why is this? Because the Scotchman has been educated at a university; his knowledge has been tested in his own university, and at Scotch universities philosophy is held in honour; whereas the Englishman has usually been educated only at a technical school, and his acquirements tested haphazard in a sort of wit combat with a viewless Board wholly unconnected with his schools. Indeed, the very existence of philosophy—the *mater studiorum*—has been unrevealed to him. And now my old friend, Mr. Wheelhouse, the President of that young giant, the British Medical Association (the only organisation of our profession which is based on broad principles and formed for a great future), member of the Medical Council of Education, and whose personal abilities mark him out as one of the most powerful men in our profession at this day—Mr. Wheelhouse proposes to make this state of things ten times worse than before. By submitting youths to a five-years' apprenticeship to working doctors at a time when their minds are expanding and impressionable, at a time when an ardent love for higher study and a yearning for ideas spring up in the heart, he would send them not where they can feel the influence of great men present and past, not where learning is seen in all her variety and in all her provinces, not where they may associate with men of their own age whose minds are occupied with other forms of culture and in training for other callings, but a student is to be confined to one mind, however able, to one profession, however honourable, to one set of ideas, however fruitful. And as a matter of fact, we know that the ruling mind will often be something less than great, the set of notions too often vulgar, and the teaching at best a teaching, and not a cultivation. Gentlemen, this is but to perpetuate the common-mindedness which I suggest is already our danger—a fault due in part to our defective education, in part to our lack of leisure. I say we are already too narrow and channelled in our thoughts, and too shoppy; and we are to improve our education by intensifying this very habit of mind. We are to make our education more comprehensive by shutting up our students with individuals; we are to strengthen their reasoning powers by therapeutical drill; we are to substitute the ideas of the middle-class parlour for the traditions of a university!

But, says Mr. Wheelhouse, your university student comes into practice so confoundedly ignorant; my purpose is, above all things, to make him an efficient practitioner, to teach him how to manage patients and how to recognise German measles. If, Mr. Wheelhouse would say, after doing this he can chatter about Shelley and Herbert Spencer, he is welcome to his accomplishments; but the broad studies must be complete. Certainly, with this I wholly and ardently consent. No one can be more opposed than I am to superficial *Schöngeisterei*—to literary fribbling and dilettanteism—in the place of solid attain-

ments and practical skill. But one may get roast pig without burning down one's house, and I contend—with an exception to be hereafter discussed—that a man whose mind has been enlarged and strengthened by a university course will, after a briefer drill, make a more skilful practitioner than one whose technical craft is gained by routine and is not vitalised by a comprehension of principles. It is no truism, gentlemen, to repeat in this place that knowledge is one and indivisible, and that he who is content to pick up isolated chapters of learning has no living knowledge at all.

The medical journals of late years have been infested by letters from qualified men, who, although not "M.D.s," desire to use the title of "Dr." They say, with a not quite ingenuous play upon words, that, being called "doctors" in a colloquial sense, they should be entitled "Dr." in the academic sense. They add with more truth that all practitioners approximate in qualification should have an equivalent nomenclature. It is difficult to see where would be the ultimate advantage of holding the title when it had ceased to be distinctive, and the disadvantages of carrying a professional label into general society seem obvious. It would be better that we should all return, like other gentlemen, to the sweet simplicity of misterhood. Meanwhile, however, the grievance is an acute one. A good student is admitted into one of the guilds of the higher class, which, knowing that they have no academic quality about them, honestly decline to allow their craftsmen to use university titles, while an inferior student slips into the profession by way of one of the guilds of the lower class which may have no such honesty, and are said to have connived at the irregular use of university titles. Straightway the worse man puts "Dr." on a red lamp by the side of his better brother, who has to content himself with "Mr." on his more modest brass plate. Nay, further, some universities have degraded themselves *pro vice* into mere examining boards, ignoring the truth that a university degree signifies a formation of mind, a habit of thought engendered by living within the influences of an organisation of all faculties; ignoring the truth that graduation signifies a life, and not a mere register of proficiency. These universities have given degrees without the residence which alone can give character to the student. The mischief all this does is not yet fully seen, although the more thoughtful men of our profession are now aware of it. Not the least of its harm is the baneful effect which it has upon the older universities, which, as at Cambridge, are driven to compete for medical students, not only by the most excellent method of enlarging and improving their apparatus and cheapening costs, but also by the less excellent method of narrowing the scope of their training.

Everywhere an endeavour is made to pursue two incompatible courses—namely, at once to keep up with the vast extension of professional studies, and at the same time to shorten the student's career. To strive with this impossibility men are brought into special studies at an earlier age, and a due civil and philosophical training is denied to them. I am not one of those who regard the classical as the only real education, any more than I so regard the scientific; neither alone suffices. An educated man cannot become so on one study alone, but must be brought under the influence of natural, civil, and moral modes of thought. The late Rector of Lincoln, to whose paper on Oxford Studies, published in 1855, all educational reformers are deeply indebted, then spoke as follows: "The necessary tendency of advancing civilisation is to divide and subdivide the applications, as of labour, so of thought. The professions tend to split up into branches, and skill in one becomes more and more incompatible with skill in another. The more a subject has been explored, the more time does it take each succeeding student to follow the steps of his predecessors. To prevent the disabling effects of this specialty of pursuit it becomes the more requisite to secure at starting a breadth of cultivation, a scientific formation of mind, a concert of the intellectual faculties ..... Clear-sightedness, sagacity, philosophical reach of mind, are to a great degree communicable by training. ..... The difficulty is to get mental cultivation recognised at all by those who have it not. Cleverness, talent, skill, fluency, memory—all these are understood and rated in the market. A cultivated mind, just because it is above all price, is apt to be overlooked altogether. It argues some discernment and a considerable degree of education in a society in which such gifts are even appreciated as useful. And let it once establish itself, even under false pretences, such is its marvellous ascendancy, that, like refined manners, it will conquer, and propagate, and extend itself by sympathy, by imitation, and, above all, by education. In this subject, eminently, it is true that the beginning is everything." These, gentlemen, are words of rare wisdom. Lay this foundation first, put your trust in this, and technical training will come far more rapidly, far more efficiently, and far less wastefully afterwards.

I have hinted, however, that there is one special case in the teaching of our students—a seeming exception to the common rule of mental training first, and technical training second—namely, in respect of the practice of surgery, not in its more abstract functions, but as a handicraft. It is a commonplace in the profession that a philosophical surgeon and a fine operator do not always coexist in the same person. No doubt manual skill must be taught from youth; and in the education of a surgeon, therefore, if not of all persons, some means, not necessarily anatomical, are to be taken from an early age to confer delicacy and dexterity of handling. But you will say we cannot afford all this; *il faut vivre*, and we have neither time nor money to spend on real studies; we must go for bread. Well, then, gentlemen, you have to take a back seat. But is this so? In the first place, excuse my rudeness, but it may be with you as with the *Ewig Weibliches*—the eternal womankind—you are lovely, but there are too many of you. The meshes of the net may be too large. As was said of the profession of the law, there is some room in the upper storeys, but the basement is crammed.

I am sure we could ill spare any one of the ingenuous faces I see before me; but, when you have well sped, you will come over to my side as regards the propriety of largely extending the curriculum, both in respect of preliminary and of special education, even at the cost of lessening our numbers. As it is, we make ourselves, by our very numbers, the prey of the hucksters who too often form the majorities of our local councils, and who are able to point triumphantly to piles of applications from highly qualified men driven by the increasing competition in the ranks of the profession to find rest in any quiet place outside it, however meagre the pay.

Urban or district councillors, conscious of their ability to be as good doctors as any of us, had they not better avocations, say publicly that any handy man can do the sanitary work of a city or a province. They decline therefore to pay for supererogatory qualities. The greatest danger in the future of democracy is its blind hatred to payment for special mental ability; men of but a little more than average ability are scarce; they are a natural sport, and should be selected. They should be secured for the public services at the price of their scarcity and of their profits in private adventure, for none is more wasteful than a dull official person. Your vestryman, however, values all other men at a rate a little under his own. He will boast one day of his success in cutting down the doctor's salary, and on the next expends £1000 upon the researches of Mr. Mullins. In Bunyan's dream, Messrs. Simple, Sloth, and Presumption lay asleep a little off the path with fetters upon their heels. Unhappily, they are now awake, their fetters are struck off, and they are put upon the jury of Vanity Fair, and that brisk lad whom the pilgrims met coming down the crooked lane from the country of Conceit, and whose name was Ignorance, is the justice's clerk. Public bodies dare not evade the charges of the lawyer. Both at home and in the city good law means money, and bad law is too soon found out and Demos discredited. But the evils of bad sanitation are not instantly obvious to the people. Pestilence and death are good old customs with which it is rash to meddle in an innovating spirit. Collectively we call them Providence, and it may be blasphemous to talk of evading them. In any case our sanitary mistakes are soon buried underground, and by the widow and the orphan are remembered in silence. So, unchidden, the tradesmen who too often govern us can satisfy their jealousy of scientific men, and boast in the market place of their penny wisdom.

Now, gentlemen, what is our defence? To turn a saying of Coleridge, we must create the taste by which we are to be appreciated. We must lay hold faithfully of Mark Pattison's words that "such is the marvellous ascendancy of mental cultivation that, like refined manners, it will conquer and propagate and extend itself by sympathy, by imitation, and, above all, by education." But you may

say, is it not an impertinence in me thus to preach a university education to students who cannot as yet all enjoy it? Is it not an unkindness as well as an impertinence? I trust not. It is in no play with words when I say to you that you are all members of that chief university—the world. This world-university has indeed one drawback. Like Peruvian bark, there is much husk in it, and it needs two stomachs to digest it. The university of the world, gentlemen, has much husk in it, and needs the time of two lives for its digestion.

In local universities, therefore, we form microcosms; we select and compact the properties of the world in alkaloidal forms, so that worldly wisdom may be taken in more readily and less wastefully. When these local universities cease to represent universals—are no longer of the essence of the living world from which they draw their being—they grow sterile as Oxford in the last century. You have then in the world at large that education of which a university is a compendium. This all of you have; it may be less convenient, but it is even more efficacious if you can use it economically. Now, of young men, the world means for one Ouida and the Vaudeville; for another, Mr. Burne Jones, Mr. Oscar Wilde and "Ballades in Blue China;" while for a third a pair of white-legged chestnuts and the prescription of bread pills for old ladies make life itself. Charming things all of them, but not universals. If the world is to be your university, your selection must be early and rigorous. Virility, imagination, and intellect must come first, and if then you retain a taste for trappings and pedlery, they may come afterwards.

When I began to practise, or rather to offer to practise, I had a large share of the contemplative life, and by good luck I turned it to account. I read three books to enlarge my medical mind—namely, Grote's "History of Greece," Gibbon's "Decline and Fall," and Mill's "Logic." Rather by accident than by design, I fell upon these three; but if to these can be added some great work of imagination (every man who has been at school can keep up his Homer with but a little trouble, and in any case has Shakespeare at his side), I think no finer culture could be had. This every student can do. This, and far more than this, an old friend of mine determined to do and did in the spare hours of a practice perhaps the most exacting and unrewarding I have witnessed. So, gentlemen, you may attain to the university mind even if you have not been rubbed against university bricks. But ere long I trust the largest and the richest city in the world will do what Yorkshire and Lancashire have done in their degree—will establish the largest and richest university in the world. Those who see farthest are now calling for it, and it is coming, but, I fear, not during your curriculum. What a chance now for a millionaire, or even for a demi-millionaire, to evade oblivion!

Acquit me, then, of any charge of shrewishness in the words I have spoken, words spoken in sympathy. I trust, indeed, when with returning steps you issue from these gates again into life, that you will show yourselves men as practical as the President of the British Medical Association can desire. It shall be no fault of St. George's if you do not. Nevertheless, I agree with Mr. Wheelhouse that an apprenticeship to the domestic side of your work, a familiarity with its lesser marks and byways, is necessary. These we cannot teach here. After your faculties are trained and strengthened in their main branches, your lesser shoots shall be duly laid in. But with capacities thus enlarged, one year's apprenticeship would do the work of five in earlier age; and an obligation upon young men thus to apprentice themselves before the completion of their studies would have my approbation and active support.

At Cambridge there used to be a step called the Licence to Practise, which was not granted until a year had elapsed after first graduation; this step, now disused, might well be revived in the manner I have indicated. And, thus apprenticed, you would not only receive, but give also. The practitioner who received you would, while finishing your dexterities, learn, in his turn, the freshest ideas of the schools; an ever-new and eager young graduate, year by year, would quicken his thoughts, and not permit them to become atheromatous. Fancy yourselves, gentlemen, not bottle-washers, but missionaries *in partibus*—ministers of light!

Man, like an ant or a rook, is a social animal. Alone he withers, in society he organises himself, and compasses his ends. Mind impregnates and quickens mind, none suffices for itself. Men say, and say ungenerously—not regarding the kind of our art, not regarding the temptations of our calling—See how these doctors differ, see how they love one another! We, and not we alone, gentlemen, give cause for these gibes; let us give cause for gibes and japes no more. We differ from each other in part because progress depends upon differentiation, but in part because we are not large-minded enough to see the principles of things. We have gone through a fixed routine of education which hampers us. We do not see that, if a man really understands his subject, he is able to make that understanding clear to intelligent laymen. We too often pronounce opinions rather than enlighten our subject. "Knowledge and opinion," says Hippocrates, "are two things; the former begets knowledge, the latter ignorance." Where the remedy for this lies I have shown at too great length already. Then we mistrust each other. Why? Because medicine, of all callings, demands the most sensitive personal honour, the most vigilant regard to others, the closest brotherhood; more than divinity, because it is practised for gain; more than law, because it is practised in the closet and not in the forum under the eyes of men. In no profession is selfishness more tempting, in none is detraction more easy and more secret, in none is smartness more immediately rewarded, in none is a vulgar ideal so glittering, or worldly success so near the hand of supple and talented persons. Nowadays we "manufacture our celebrities as we go on," and the pet of the monthly reviews, always something less than the best, is run after by the public with ovine sequacity.

I, who have been in the thick of the fight, now standing aside, may speak more plainly to you than I could do when my own gain or emulation might have seemed to disturb my vision and to warp my sentiments. *Spectatum satis et donatum jam rude quæris.*

I will venture, then, before we part, to offer some advice to those of you who will soon enter life. You will find that, both in respect of competition and of consultation, the elements of mistrust are not inactive. The temptation to score off another man's openings seems to some persons irresistible in spite of the certain turn of the wheel against themselves another day. Perhaps they hope to win on the average. How mean it is! How mean even between rivals! But for a consultant to act thus by word, or even by look or gesture, is cowardly and base indeed. At the moment the consultant has enormous power, and should therefore err on the side of generosity, especially in the absence of his brother practitioner. And yet who does not know the raised eyebrow, the shrug, the "I could an' I would" air of the fashionable consultant, as he listens condescendingly to the patient's report of his own doctor's opinions. *Salus agrotantis suprema lex.* The patient's safety is before all else, that must be clearly posited, but his safety rarely comes even into pretence. The occasions are very rare in which the safety of the patient involves a breach of consent between his doctors. In my experience a family attendant was always very glad to try any plan of treatment which seems reasonable, and it is the duty of the consultant, where treatment is manifestly changed, to speak of the change, not as dictated by himself, but as the result of a joint consultation. In most cases he can truthfully add that a change would not have been made unless the previous treatment had been well tried in vain. Changes of diagnosis, except in case of grave error, can usually be developed gradually, so that sudden declarations of change of opinion are avoided. But the public may say, Is this reticence fair to us? Certainly, if the patient's interests be safeguarded, that is, if the doctor in charge be not an ignorant fool or a shifty knave, and in these cases the consultant must, by letter or visit, keep a sharp eye on the progress of the case—the reticence is not only harmless to the patient, but of the greatest value to him. Nothing does a sick man more harm than to have his confidence shaken in his doctor, and to swap horses in mid-stream is rarely desirable. Even where a difference between two medical men is irreconcilable—and such cases have occurred to me from time to time—the difference can be amicably arranged. In thirty years I never had to supplant my brother on this account. The family doctor must be charged with the duty of setting forth the difference to some sensible friend of the patient, and in my experience this has always been done most conscientiously. Such cases are usually obscure and difficult, and it becomes the consultant in his turn to point this out, and to express a willingness to call in a third physician to aid in the decision. If all parties are straight and unselfish, these diffi-

Digitized by Google

culties are readily adjusted. Indeed, with seasoned practitioners, consultations are always smooth, and nearly always welcome on both sides.

It is you touchy young men, just out of the schools, who give us the trouble—who bridle up at the suggestion of a consultation, and declare that nothing more can be done. An older man knows that a good talk over a case is, at any rate, a pleasant meeting, and probably valuable to him at least in bringing about an orderly revision of the symptoms and in refreshing the confidence of his patient. He knows, too, that when a doctor is sick himself he calls out for a consultation sooner than a layman does, and runs from one doctor to another in defiance of all convention. I never knew a sick doctor who failed to consult at least three London physicians in a forenoon, usually concealing from each his visit to the others. The fact is, life is dear not to doctors only: to me it is marvellous, not that patients slip off to consultants, but, with the fear of death before them, they are so loyal to their own advisers.

Always, then, welcome consultations. Anticipate, if possible, the patient's wishes in the matter, or, at any rate, the wishes of his friends. Never repeat the silly boast, "My patient has such confidence in me he does not want a consultation." I used in secret to hear rather too often the other side of that story, and if the patient should not want it, you ought to want it. The public is right in regarding a consultation as at least a tribute to the sacredness of human life, and it keeps doctors up to the mark. For these reasons, if I had my way, no man, not even a pauper, should die of acute or obscure disease without a consultation. State clearly always whom you consider would be the best consultant for the case, but, having done this, meet any honest man the patient really wishes for. In the height of my practice I gladly met any of my juniors, even my own pupils, if things pointed to it; and very pleasant consultations we used to have. At the same time, it is better that professed consultants should not only, of course, never visit any patient alone, but should even discourage frequent calls at chambers if the visits, losing the feature of consultations, begin to merge into sole charge. Under such circumstances I always regarded it as my duty to suggest that an ordinary attendant should be selected, and consultations held as occasion required. But I regret to add that often I never saw the patient again.

I cannot wonder that an honourable reticence has less attraction for us, that a calm and patient temper seems too slow for us, and that the bonds of fraternity are weakened, when self-seeking, ostentation, and *finesse*, if they do not take men into the first rank of our profession, at any rate make a very good thing for very many of them. The spirits of the faithful have thus been tried, not in our day only, but in all times of luxury and pride. But perhaps in all ages, certainly in our own, I am thankful to say that purity, disinterestedness, and devotion not only bring peace with them, but even in the world itself surely win that success which a wise man would seek.

We of our generation prevailed over our fathers, you in your turn will prevail over us, and a mightier reaper shall prevail over us all. Our fathers called us into these halls, and set before us the record of a noble tradition, the example of noble life; we call to you, and you shall call to your children, and thus, so long as sickness and sorrow abide amongst us, we frail men of a day shall still raise our eyes to that lofty conception of our duty which Hippocrates himself set forth in the first chapter of his scriptures, a conception which, with all our shortcomings, I trust and believe has been handed on by his successors undimmed and undefiled to this day.

OPEN SCHOLARSHIPS. — *Guy's Hospital:* The Open Scholarships in Arts have this year been awarded to Mr. William S. Handley, Loughborough Grammar School, and Mr. John Robert Steinhaeuser, Sutton Valence School. The Open Scholarships in Science have been awarded to Mr. John A. Howard, King's College and Guy's Hospital, and to Mr. Arthur H. Leete, University College, Aberystwith. — *St. Thomas's Hospital:* Open Scholarships in Natural Science: First, value 125 guineas, awarded to Mr. T. G. Nicholson; second, value £60, awarded to Mr. A. E. Russell. — *St. Mary's Hospital:* The Open Scholarships in Natural Science have been awarded to Messrs. H. J. K. Bamfield, A. W. Sanders, A. Stanley, and A. E. Wilson; and the two University Scholarships to Mr. A. Senior and Mr. A. E. Shaw, both of Cambridge.

Introductory Address.

A PLEA FOR "THOROUGHNESS."

Delivered at the Yorkshire College, Leeds, at the opening of the Session, October 1st, 1889,

BY W. T. GAIRDNER, M.D. EDIN.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW, PHYSICIAN TO H.M. THE QUEEN IN SCOTLAND.

GENTLEMEN,—Some few weeks ago I read in a newspaper somewhere a paragraph, which, whether written in jest or in earnest, I thought at the time might be made the text for some remarks more or less suitable to the present occasion. You will perhaps laugh at me, or suppose that I am laughing at you; but at all events I will pray you to laugh *with* me, when in the presence of this august assembly I venture to read the said paragraph. Here it is:—

"AN AUTOMATIC DOCTOR.—A Dutch apothecary has just taken out a patent for a novel automatic machine in the shape of a wooden figure formed like a man. The figure will be covered with compartments labeled with the names of various ailments. The sufferer has only to place a piece of money in the compartment upon which the name of his illness is inscribed, and forthwith will appear a pill or powder suited to his case. The machine is constructed upon the same principle as the ordinary automatic chocolate and bonbon machine. A Dutch paper predicts a brilliant future for this very original doctor."

Now, I am not going to ask such of the young men now before me as are applying themselves to medical study, "Is this *your* ideal?" That would be not only too absurd, but even (but for its absurdity) insulting to an audience whom I am desirous above all things to attract and to please. But I am entitled at least to ask, Why is this *not* an ideal form of medical advice and prescription for a considerable proportion of those who may require such aid in sickness? In the attempt to answer this question, I believe we shall find a few nuts to crack which may occupy us profitably for some portion, at least, of the time usually devoted to an address such as this. Think, in the first instance, of the immense comfort and convenience of the proposed arrangement. Why, you might have these machines at almost every railway station, always ready for use just as you pop your penny into the slot when in quest of a cheroot, or of the wax vestas to light the same! Only, let us hope, for the sake of the poor doctors who are not automatic, that the "piece of money" to be automatically administered—the fee, in fact—would never degenerate lower than half-a-crown! With this proviso, one seems to see how the thing might work tolerably well in some cases. There are a good many of the "thousand natural shocks that flesh is heir to"—perhaps even a majority of them—very easy to name and very well defined indeed to the sufferer. And some of these are, moreover, very easily put a stop to, if you take them at the very beginning. "Principiis obsta"—here you have it all made clear to the most ordinary capacity; no trouble, no nervousness, no hesitation nor procrastination, no embarrassing or uneasy confidences with a man of skill, only half-a-crown in the slot, and there you are! Liver, stomach, heart, lung, brain, biliousness, colic, blood-spittings, rheumatism, neuralgia — all under control, without a moment's delay, and by the most approved remedies in each case, at every railway station, and in every public place! Surely there is something to be said, *primâ facie*, on behalf of such an arrangement as this!

I am pleading, you observe, the case of the "automatic doctor" as against the living, flesh and blood doctor, in these words; and some of you who are readers of Carlyle may be reminded (*longo intervallo*) of the severe, almost savage, irony (worthy of Dean Swift) of his proposal to substitute "cast-metal parsons" for our spiritual guides and instructors. In both cases the suggestion proceeds upon the lines of economy and convenience; and further, on the assumption that the automatic is nearly, if not quite, as good for certain purposes as the living article. But it might further be maintained, in the case of the "automatic doctor," that it is by no means a necessary part of the case that the machine-made should entirely supersede, or even replace, the living doctor of medicine. If some more or less

Digitized by Google

fastidious persons object to be prescribed for anonymously, why should there not be an acknowledged, even a distinguished, living authority behind the dummy? or even more than one? Fancy a well-organised group of "automatic doctors" (perhaps with some distinctive uniform) literally doing the work of Sir William Jenner or Sir Andrew Clark (so far, at least, as prescriptions go) in every railway station in England, by carrying the most famous and successful of their acknowledged recipes, ready made up, in the most economical way possible, to almost every sick person who can define his own ills to himself sufficiently to profit by their skill thus imparted. I am assuming, of course, that there will be a copyright in the recipes thus used, and that the law will protect the authors of them from piracy; so that an automatic doctor who may represent a great physician by using his recipes shall do so only by previous arrangement with him. Can there be a doubt, do you think, that very considerable professional incomes might be made in this way? and that hundreds, nay, thousands, of comparatively poor persons would eagerly avail themselves of the help that could thus be had at every man's door, without a visit to London or from London, and a correspondingly heavy professional honorarium?

You will allow that I have argued the case of the dummy or automatic doctor at least as well as the newspaper from which I derived my information; and, indeed, so as to present it with every possible advantage and in the most really professional form attainable, or perhaps imaginable. I will now proceed to inquire a little more seriously what it is that hinders a manner of treating disease like this from being habitually adopted—or, at least, admitted frankly as in accordance with an enlightened medical opinion? For we may take it as certain that the "automatic doctor" carrying the authority of Sir William Jenner or Sir Andrew Clark is just as remote a contingency as would be Carlyle's "cast-metal parson" doing the work of either Canon Liddon or Mr. C. H. Spurgeon. Why is it, in other words, that in matters of health and disease there is not only no possible substitute for the living man as a counsellor, but that even the living man, to satisfy the just expectations of an enlightened public opinion, must undergo the training, acquire the experience, and generally go through the hard and life-long discipline alike of intellect and of character, which you, my young friends, are now only beginning to appreciate, and which finds its final expression in some of our greatest physicians and surgeons.

Had it been even possible to formulate adequately any considerable portion of the medical art in the manner required for merely mechanical prescription, not only would this have been done long ago, but the progress of the ages would have given such stability to the results that the treatment of disease in this nineteenth century would have been mostly stereotyped (as one might say) beyond the possibility of change or revolution. Instead of this we have the curious fact evidently before our eyes, that in no previous age of the world has so little importance been attached to formulæ, or so much to the labours, experience, and opinions of individual men dealing with disease, as in the present. I am not speaking, observe, of disease as matter of doctrine, or as treated of in books, or in the lecture-room, but disease as occurring in the sick chamber or hospital. You will find it, I believe, to be the simple truth that at no time in the world's history have the medical advisers of the sick been so little hampered by traditions as at present; at no time have the methods, the formulæ, the remedies of past ages undergone more revolutionary changes, and yet at no time have the living influence, the character, the personal status of the physician and surgeon been more adequately maintained than precisely in this latter end of this nineteenth century of ours. So much is this the case that if you take up a book which represents the traditions of even less than half a century ago, you will find these traditions almost entirely superseded, and even hopelessly out of accord, on many points of the first importance, with the matured opinion of almost every one of our greatest masters of the art at this present hour, either in England or in any part of Europe. Not one in a hundred of the medicinal formulæ so copiously scattered over the pages of Copland's Dictionary, for instance, obtains any considerable amount of favour or support to-day; not one acute disease, probably, is treated as he and the greater number of his contemporaries would have treated it; nor is there a single article, perhaps not a single page, of that immense and voluminous work, on which the merest tyro of to-day would not be amply justified in writing numerous emendations and improvements, founded on the instructions and experience of a four-years' medical curriculum; and yet medical opinion, as such, and especially individual medical opinion and influence, far from losing in weight owing to this prodigious amount of destructive criticism and revolutionary change, are of wider scope and further reach than ever before. On all this, considered as historical fact, I have had to expatiate a good deal of late years in various addresses and papers, some of which have lately been collected into a volume.[1] I am therefore the more disposed, in the present instance, to forego the argumentative defence of this position, and to assume it as proved, in order to make its consequences instructive, if possible, for you.

One consequence of this state of things I have already foreshadowed, or rather have affirmed—viz., that *real knowledge*, by which I mean something quite different from learning, or hearsay evidence of mere opinion, about disease and its cure, counts for more in the individual man, even in the most ordinary general practitioner, than it ever did before. Not so very long ago it was possible for a man with a very ordinary amount of industry and of scholastic attainments so to saturate himself, as it were, with the doctrine of a particular teacher or school as to command a certain amount of attention and respect for opinions enunciated in terms of that doctrine, however remote they might be from the facts of a case under observation at the moment. The fever in this man (an actual patient) was, on very slender evidence, adjudged to be a malignant, or a putrid, or a low nervous fever; it arose from this or that depravation of the humours, this or that *materies morbi*, this or that entirely suppositious or hypothetical change in the blood, in the nervous system, in the solids of the body, according as the man speaking to you was a humoralist or a solidist. A very few obvious indications sufficed here for the diagnosis—i.e., to enable the fever to be placed in the nosology, and so to get a name. The treatment followed almost as a matter of course from the name, or rather from the theories or hypotheses connected with the name, according to the school or system of doctrine in which the observer had been trained. Now, I am far from saying that this method of viewing and of treating disease is altogether extinct, even at the present day; but I am free to affirm that it has been very much modified. Any one of you, gentlemen, after even a four-years' curriculum, will be in a position to form a far more direct, sounder, and less ambiguous judgment upon many cases of fever and acute disease than any man who wrote at large upon them, even in the first third of the present century; because you will have to apply tests, and to use methods of observation, and physical means for the detection of local changes, which were then almost unknown. Do not let this assurance, however, make you conceited or contemptuous of our forefathers; there is still plenty of room to say that neither they nor we have anything like a complete knowledge of any fever or any acute disease.

When I hear a man talking at large and dogmatically about "biliousness" (a term of Abernethy's, which neither Abernethy nor anyone else has been able to explain further than that it requires blue pill), or about "congestion of the brain," or anæmia of the same, which he cannot have seen, and does not know at all as really existing, or about "irritation of the mucous membrane" (so beautifully vague that it may mean almost anything), or about "hyperæsthesia" or "hyperæmia," or, to use a more modern phrase, "neurasthenia"—I know that he is in the stage of mental progress represented by those old theoretical views of the fevers to which I alluded a moment ago. He is using words, not to set forth knowledge, but to conceal and gloss over essential ignorance; his diagnosis, and prognosis, and treatment will probably all follow the same lines, and be based upon some intangible theory or current hypothesis of his own or someone else's invention, and not upon the plain facts and carefully studied details of the case before him. Therefore it is that I urge upon you young men to get into the habit of steering clear, if possible, of all such mere vague and misleading phrases. Try to think of diseased phenomena as men do who have and who use (up to a certain point) the means of *knowing them as facts*, and not merely *speculating about them;* men armed with the stethoscope and ophthalmoscope, and laryngoscope, &c., and with chemical and microscopical tests at hand, and the thermometer, sphygmograph, &c., to give the exact indications of fact,

[1] The Physician as Naturalist, 1889. Glasgow: James Maclehose and Sons.

Digitized by Google

which should place you out of the bearing altogether of these survivals of ancient, sometimes even of mediæval, theory, which may for a time usurp the place of medical science, but are no more closely related to real knowledge—that is to say, the true *science*—of disease than the atoms of Democritus and Lucretius, or the Vortices of Descartes, are entitled to rank as physical science in the modern acceptation of the words.

Now, the attitude of mind which I am commending to you (for as a mere attitude of mind it is of more value to you than oceans of "cram," or even of crude information about disease, in respect of your future career) must be cultivated; and it must be cultivated early if it is to rule in any considerable degree your education as medical students or practitioners. This is all the more necessary to be said—indeed, to be insisted on—because the opposite attitude, which for distinction's sake I will call the "automatic" attitude, is still widely prevalent, and is much more easily learnt. It did not require the suggestion of an "automatic doctor" to teach us that much of our casual prescribing is, as it were, or was not long since, done by machinery or by rote.

It is very easy to lay hold of one or two leading symptoms or complaints and to call them a *disease*. It is very easy then to take down a little book of *formulæ*—it may be the recipes of very distinguished physicians; to look out the appropriate *name* of the disease supposed to exist, and then have a shot at it with the first *recipe* that comes to hand. That is what I am calling the automatic method. But the true physician knows that the diseases of our poor humanity in their ever-varying aspects are not thus to be formulated; and further, he knows that what he has got to treat, and to cure, if he can, is not the *disease*, as regulated and named by custom, but the *man who is afflicted by the disease*—the whole man, and not only a part of him; all his disordered functions or altered structures, and not only the particular point where he feels the pain. Therefore it is that the "automatic method," easy as it is in many cases to learn and to apply, will not do even for this nineteenth century, and will be thoroughly exploded in the twentieth. Easy? Yes, but just because it is easy it is correspondingly fallacious. It ignores, or sets aside without due consideration, all that a more carefully disciplined modern physician places in the front rank of importance—hygiene, the inquiry into causes, and treatment of the highest order depending upon these. It recognises only the disease and its assumed antidote—and thereby for the most part fulfils Voltaire's well-known sarcasm, that the art of medicine consists in putting a number of drugs of which one knows little into a body of which one knows even less. There is a fatal facility in this method, which has made it specially appropriate for quacks in all ages. To use the words of Hamlet to his faithless friends, Rosencrantz and Guildenstern, when the latter declares his inability to play upon the pipe—"'Tis as easy as lying: look you, these are the stops. Do you think that I am easier to be played upon than a pipe?"

I do most earnestly trust, gentlemen and students of this medical school, that, between those two contrasted attitudes of mind as respects disease and its cure, you will decide early, and be safely guided by your teachers as to which you are to choose. For upon the choice you make depends almost entirely (apart from more individual moral and intellectual characteristics) whether you will be found really advancing the art and science of medicine, or whether you will be of those who sink deeper and deeper into the ruts of routine practice and retrograde theory as life goes on. But I cannot persuade myself for a moment that in a school which can boast of three or four generations of such distinguished and progressive surgeons as the Heys and the Teales, and which even to-day and yesterday has, or has had, such leading spirits as Clifford Allbutt and Wheelhouse, there can be a moment's doubt as to your decision. With such traditions and such examples before you, it is morally almost impossible that you should become, or wish to become, "automatic doctors." I will only in a few words point out to you what is, in my opinion, the most important kind of discipline for enabling you to tread successfully the straight and narrow way that leads, not to the attainment of a high and varied medical culture (as to which you must, in the main, depend upon your teachers and on the authorised curriculum), but rather to the state of mind which alone makes such attainment possible. For you must take it from me that at every step in your career the "automatic doctor," in one insidious form or another, will stand athwart the path of progress, and may even, with some of you, tend to stifle the nobler impulses by proving how very successful he is—with the public. From the merely lucrative point of view, there are but few even of our most successful physicians who could compete with the highly automatic money-making machinery of Holloway's pills and ointment, or old Dr. Jacob Townsend's sarsaparilla. From any other than the merely lucrative point of view, and happily, in the end, with most of you (I trust), even from the point of view of a reasonable worldly prosperity, it is most undesirable that you should yield, in the very slightest degree, to this insidious form of temptation.

Now it is at this point that I find it needful to have a very few words with my friend Mr. Wheelhouse, not, I trust, inappropriate to the present occasion, concerning some of the remarks which he made here a few weeks ago in that most admirable address of his, as president of the British Medical Association. I do not suppose at all that we differ greatly in essentials, or perhaps even in details; certain I am that we have both one object at heart, the advancement of our profession, alike in its essential usefulness and in the good opinion generally entertained of it; which, indeed, forms a part, and a large part, of its usefulness to the public. But some of the remarks in that address appear to me to be open to an interpretation which possibly is not the one intended, but which at all events I desire not to allow to pass current without a *caveat*. It seems to be assumed or suggested that, in order to keep a medical education upon what are supposed to be *practical* lines, it is necessary that every student, before getting his name on the Medical Register, shall have had opportunities of seeing, handling, and in a certain sense treating, almost every kind of common disease and every ordinary type of infectious fever. By parity of reasoning, it would equally be necessary, as a security to the public, that every man admitted to the Register should have done every minor, or even possibly every ordinary major, operation, so that nothing should come to him hereafter so as to find him quite devoid of previous experience. Now, while I am as anxious as Mr. Wheelhouse or anyone else can be to improve, in every reasonable sense, the practical side of a medical education, I venture to say that what I have now put into words of my own as being suggested by the address referred to is not, to my mind, even a good practical ideal. Moreover, if any such ideal is to be carried out, or attempted, it will be absolutely necessary for the General Medical Council to go back on their late resolutions with respect to the "covering" of unqualified medical assistants; for, without some sort of "covering," lawfully or unlawfully, how is this extent and variety of practical experience which is regarded as essential ever to be attained by the majority of students or of undergraduates? It will be conceded that in order to make an experienced as well as a properly instructed practitioner, it would be requisite that he should have had opportunities of setting fractures and reducing dislocations; of performing venesection; of passing the catheter, not only in the normal subject, but through strictures and other difficulties; of treating and of observing throughout, with a certain amount of responsibility, cases of measles, pneumonia, typhus and typhoid fevers, phthisis, small-pox, rheumatism with and without cardiac complications. Why not also of performing operations in strangulated hernia, tracheotomy, ligaturing of arteries and veins, and other cases of emergency which, according to the programme just referred to, ought, if possible, to form a part of the training necessary to fit a man completely for all the necessities of general practice?

I apprehend that it is only necessary to put the case in this form in order to show that there is a fallacy somewhere—I do not say in Mr. Wheelhouse's argument, but in the conclusions to which I suppose his argument will, if carried out logically, apparently lead. I will therefore here affirm that my own view of what is essential to a practical medical education differs in some respects from that which I have presented above, using (it may be erroneously) the name of Mr. Wheelhouse. Speaking from my own experience as a teacher, I hold that the hitherto unsolved problem of a perfect medical education is to be sought in a direction nearly the opposite, or converse, of that just indicated—viz., *not* that the student or candidate for a diploma should have seen and done personally almost everything, or even many things; but that he should have seen and done comparatively a few things in such a way as to give a proper foundation or leverage, as it were, for attempting successfully others which have necessarily lain outside the possibilities of a young man's experience. And accordingly I have come to regard it as of far greater importance that

Digitized by Google

every case observed or dealt with in any way by the student, or in his presence, should be *thoroughly* observed, and its treatment *thoroughly* understood, than that a much greater number and variety of cases should be so observed and so treated as to beget habits of imperfect observation and loose thinking—in short, the habits which in their developed form give origin to the "automatic doctor" aforesaid.

This general principle being affirmed (for it would be out of place, I think, to go further on the present occasion), I am content to leave the practical questions arising out of it for settlement by wiser heads than yours or mine, with only one additional remark. It has been several times affirmed by way of criticism on the present curriculum of the schools that a young man may have gone through it all, most carefully and well, and yet never have actually seen a case of measles. Well, that is a misfortune, and to the extent of my own personal influence (under the difficulties arising inevitably from recent sanitary legislation) I have always done my very best to remedy it, or even to render it impossible, in the case of my own students. But I hold it to be far less of an evil that a man should go out into practice, not having seen a case of measles, than that he should have seen, and handled, and treated hundreds of cases of all manner of common diseases, after the frisky manner of Mr. Robert Sawyer and Mr. Benjamin Allen, the undying literary types of the *ancien régime*, under the system of compulsory apprenticeships. And I sincerely trust that, if any attempt is made (as seems likely) to restore to the medical curriculum whatever may have been good in that system, it will be under such wholesome regulations as to time, place, and manner as will effectually give substance and reality to the instruction afforded, and avoid perpetuating in a new generation, or perhaps in two or three of them, the routine practice, and the slovenly and hasty diagnosis, which could alone make the suggestion of an "automatic doctor" a possible thing.

These, however, gentlemen, are considerations not for you (at least in this stage of your career), but for your seniors, and especially for the General Medical Council, and Mr. Wheelhouse as an influential member thereof. I trust I have not in any way exceeded the bounds either of duty or of courtesy in submitting to you and to him these remarks (somewhat longer, perhaps, than I intended) on this most important subject. What remains for you to do is to avail yourselves fully of the splendid opportunities that lie open to you in this medical school and in your magnificent hospital, for laying the foundations, both broad and deep, of a medical discipline that will stand the strain and support the weight of the responsibilities that will by-and-bye be laid upon you. How this is to be done in detail I have already considered in several of the addresses included in the volume I spoke of, and of which this is in part the echo in a somewhat different form. The gist of it all is that the instincts of the naturalist, the love of nature and of fact, the reverent study of the laws of biological science, and of the physical sciences which underlie the phenomena of living as of all other matter, form the salt which redeems all our professional work alike from barrenness and from falsehood in principle. You first encounter these laws and phenomena in your study of chemistry and anatomy, zoology and botany. I advise you to lay the foundations well *there*, and by no means to lay the flattering unction to your souls that any of these are *useless* studies, because they seem not to be immediately *practical*. Apart from their manifold applications in practice, they are of untold value as a discipline. And, as I have insisted elsewhere, this discipline at an early stage of your medical career is of special importance, because it is of a kind almost overlooked in much of your earlier school education. What you learn in these scientific departments—always supposing that they are taught practically, and not *only* in books and lectures—is to come to a closer grip with Nature and with fact, and not to be deceived and deluded either with false shows or learned philosophies and philosophisings. And this is a kind of knowledge, *the knowledge of things as opposed to words and abstract ideas* (for so Michael Faraday called it), which is often greatly deficient even in educated minds, and the want of which is felt at every stage of a medical career. Let *thoroughness*, therefore, enter into all your dealings with these earlier studies—those of your first and second year. It is not merely that you are gaining *information*, but that you are *forming habits*.

Then, as regards the application of the habits so formed to your studies in medicine and surgery proper, I will ask you to-day to receive, and to ponder, only one or two suggestions from a teacher, some of whose early pupils are now grey-haired practitioners. I do not propose to speak of doctrinal instruction, the value or even the correctness of which depends largely on the teacher, but only of clinical instruction. In this, as in everything else, there is a right way and a wrong, and the difference between the two ways consists almost entirely in what I have called *thoroughness*. If you learn *thoroughly* to know even *one* case—diagnosis, prognosis, treatment, and all about it—in a humane as well as a scientific spirit, you may rest assured that you have got something which will remain with you all your life. If you learn, otherwise than thoroughly, to know after a fashion a great many cases, you have also got something that may remain with you as a life-long possession; but that something is simply a bad habit of working, while in the other case it is a good habit, and, over and above this, a valuable addition to your positive knowledge. I can remember now single cases seen by me forty years ago, and some of them are so printed in the memory that they have all the vividness, as well as the value to me, as though they were of yesterday. Now, I am going to say to you what may seem to be, but is not, a reflection upon particular teachers or pupils. There is a way of perking and pluming one's self upon a *diagnosis*, as who should say, "See how rapidly and surely I can do it; a single glance at the expression, a moment with the stethoscope, a word or two of conversation, and the thing is done, and the whole case is before my mind." This, according to my experience, is a very fatal bad habit, both for the teacher and the taught. No doubt rapidity of diagnosis comes with experience, and is not without a certain value; but in teaching, the first and the last lesson is always, or ought to be, *thoroughness;* and thoroughness, in the sense in which I am using the word now, is not consistent with aiming at these lightning-flashes of intuition. A true diagnosis risks nothing; it aims at being exact, not at all at being wonderful or rapid. Therefore it is never a thing to make a show of, or to boast one's self about; and he that does it in that boastful spirit is, in the very act of doing so, setting a bad example and teaching a bad habit.

What shall we say, then, of those out-patient rooms where twenty, thirty, or forty cases are disposed of in an hour, not only as to diagnosis, but also as to treatment? What, again, of those immensely busy practices where the mere multitude of the cases, or the distances to be traversed, make it well-nigh impossible ever to *complete* a diagnosis? Can these be considered as fit fields for gathering sound clinical instruction, or for maturing the crude experience of young aspirants whose chief desire is, according to the programme I mentioned a little while ago, to have personally seen and treated almost every common form of disease? I do not stop, as you will observe, to argue out these questions, for I have no time to do so; but I state, without the slightest hesitation, my own sincere conviction that for sound clinical teaching and for the formation of correct ways of observing, and thinking about, and treating disease—such habits, in short, as will be serviceable for a lifetime—the first and absolute rule is *thoroughness;* there must be no hurry. An hour, or even more, spent over one case (always supposing that the state of the patient admits of this) is out of all calculation more valuable than five minutes each over twelve cases, or even ten minutes each over six cases. And therefore I say again that the maxim which should guide our superiors in laying down the law of practical instruction is *Non multa sed multum;* not a great multitude of cases just seen, or very superficially observed, but a smaller or much more moderate number, the deliberate and careful observation and management of which in detail may form, as Tennyson sings, the stepping-stones on which to rise to the higher levels of a more rare, or a more difficult, or a more advanced experience.

Gentlemen, I have done. I had a good deal more that I should have liked to say to you, but the lapse of time warns me that there will be some of you at least waiting anxiously for the end of my sermon. It now only remains for me, as an outsider, to wish you all possible success and all possible happiness and efficiency in the studies of this medical school during the present session. I have endeavoured to indicate to you only the broad lines on which such success and such efficiency are to be sought. It is for you, so far as lies in you, to make the application.

God bless you all! Farewell!

ON THE DIAGNOSIS AND TREATMENT OF SCROFULOUS GLANDS.

BY W. KNIGHT TREVES, F.R.C.S.,
SURGEON TO THE ROYAL NATIONAL HOSPITAL FOR SCROFULA.

(*Concluded from page 634.*)

THE first indication in local treatment is to remove all sources of irritation. Excise the tonsils if enlarged, extract decayed teeth, treat adenoid growths, and try to cure post-nasal or pharyngeal catarrh; in short, if the glands are in the neck, try to get the mouth in a healthy condition and follow the same line of treatment elsewhere.

Local treatment to be successful must be thorough; it is a mistake to meddle with scrofulous glands unless one can get the whole thing away. I am very averse to partial operations; they often set up fresh irritation, arouse slumbering glands to renewed activity, induce increased peri-adenitis, cause fresh healthy glands to enlarge, and in fact leave the patient with a larger swelling and in a worse condition than before he was touched. If I am right in believing that the removal should be thorough, I would ask, "Can anything effect this complete removal except the knife?" I think not; the scoop certainly cannot do so; one constantly finds masses of deposit in glands which are quite hard and cannot by any force be scooped. It may be said, wait till the gland softens, but glands do not always soften, even when they are the seat of deposit, and may remain in the same chronic indurated condition for years. When the deposit does soften, the process is not generally uniform throughout the gland or glands. The softening takes place in separate glands or in patches of the same gland at various periods and at a certain stage of disease in each particular instance. It is not uniform throughout, either as regards individual glands or as regards the mass generally. If the surgeon could find and scoop out these broken-down portions, the patient would be no better off; the remainder of the affected gland or glands would still degenerate and cause trouble. Scooping alone is chiefly applicable to two conditions of the disease—viz., limited superficial gland enlargements which have uniformly softened, and old fistulous tracts kept open by withered caseated glands; it is also useful for scraping away rotten skin, old inflammatory deposits, and for clearing up generally. In the first of these conditions I am not of opinion that scooping is the best plan, as it leaves an abscess cavity which complete or partial excision would avoid. In large masses of scrofulous glands scooping alone would simply hasten the patient's end; these cases must be either excised or left to nature. I have heard and read scooping and excision compared, as if a given case should be treated exclusively by one method or the other. Practically this is not so; the surgeon has to remove all the diseased glands in whatever stage they may happen to be; some glands will be found too hard to scoop, others too soft and broken down to excise; therefore the operator must deal with the glands as he finds them, scrape some and excise others, the only *sine quâ non* being that he should clear away all the disease and leave no lumps to be felt when he has finished. I sometimes use the scoop alone, more often no instrument but the knife; a combined method of excision and scooping is, however, more generally useful than either method by itself. The skin incisions should be free and generally over the mass. If the glands are loose and can readily be shifted so as to be brought into view, one may make the skin cuts in the line of the creases of the neck; if the glands are under the sterno-mastoid, the incision should be along the line of this muscle, either in front or behind, or if the mass be very adherent to the vessels it will require two incisions in this line, one in front of the muscle and one behind. The advantages of a free skin incision are obvious: the surgeon can see what he is about, can more readily remove the whole of the disease, can satisfactorily arrest all hæmorrhage, and, finally, has good means of drainage when he has finished. Nothing is more dangerous than trying to extract glands from the neck through an insufficient opening, and it is a mistake to deal with glands through a small hole. The method of operating in cases where the glands are very adherent I have indicated in a former paper. Some glands are so loose that they can be hooked out by the finger; others can be removed by incising the capsule, some by a moderate dissection, while others will require the very closest dissection. If the surgeon has to dissect, he should always cut *on* the gland. In this way only will he avoid bleeding and wounding important structures. The gland itself is not vascular, the surrounding cellular tissue is very much so. In dissecting, the gland should be *fixed* either by the fingers, a hook, or a thread passed through it; it is not a good plan to dissect a gland which is at the same time slipping and bobbing about. When a solid caseous mass of glands is firmly adherent to the vessels, it is not judicious to try and dissect it off clean; clear as much of the mass as you safely can; slice off the greater portion, and with the fingers or scoop slowly and carefully scrape or peel off the rest. It is surprising what patience and perseverance will do with an apparently hopeless mass, and I have not yet come across a mass of glands that could not be removed—one side of a neck will sometimes take two hours. There is no vascularity in old glands. Inaccessible glands, such as those above the angle of the jaw, may have their capsules freely divided, their contents are as far as possible scraped out, and the capsules gently pulled away with forceps. After removal, resist the temptation to sew up the skin flaps, except in especially favourable cases in which the knife alone has been used. In the neck, more than anywhere else, bagging or retention means serious trouble. Adapt the flaps with the fingers and keep them in position by a sponge or antiseptic wool, which is included in the dressing. I do not, as a rule, use tubes. Absolute rest must follow, no mastication, and the head fixed by sand-bags. As regards scooping, if a gland is scooped, do not be in a hurry to allow the skin wound to close, however perfectly the gland may have been scraped and evacuated; particles of deposit remain behind, or a bit of gland may not have softened sufficiently to enable it to be scooped out. As long as any induration is left, it is well to keep the tube in or the wound open, and there should always be direct and easy communication between the skin opening and the remains of the gland trouble. In combined operations of cutting and scooping, the more the knife is used and the less the scoop the better; the knife causes less bruising, leaves nothing behind, and gives the best result.

Disorganised and unhealthy skin.—If the skin is blue, sodden, undermined, and thin, it is better to cut or scrape it away. Scraping is a test; if it is soft enough to scrape away it is of no use. It is a mistake to leave unhealthy skin under the notion that it will recover, and thus, by rendering a smaller wound necessary, diminish scarring. This is not found to be the case, and some of the puckering one often sees is due to the contraction which takes place during the process of healing in this damaged skin. Nothing but healthy tissue should be left behind, when the wound will heal quicker and leave a better scar.

In dealing with scrofulous glands the matter of scarring is worthy of consideration. Why do some cases show such terrible scars? Are the nature, appearance, and character of the scar dependent on the method which has been adopted for getting rid of the disease? Is it, if bad, due to the fact that the gland has been incised, allowed to break, poulticed, painted with iodine, scooped out, or treated in any other manner? Is a bad scar owing to the injurious influence on the healing process of the scrofulous constitution? I believe that a bad scar is not essentially dependent on one or any of these influences, but that it is generally entirely due to the simple fact that some source of irritation remains behind; that all the disease has not been removed that remains of thickened capsules, gland débris, or small infected glands are left. Nature shows her objection to this, and indicates her desire to get rid of it by a prominent, red, and ugly scar. I have seen glands excised, union by first intention with an almost imperceptible line, and subsequently this line widen. thicken, and become raised and red because other glands scarcely to be felt at the time of operation, and considered too small to need removal, have kept up irritation. On the other hand, I have often had cases in which, from destruction of skin, wide, irregular wounds were necessarily left after operation, recover with a flat, white, improving scar when the removal of the disease has been complete. If every portion of diseased gland tissue has been removed, and if there is no further infection or return after the operation, the scar will be an improving one as time goes on, but if any disease remains or returns the scar will continue to grow worse. A prognosis may to a

Digitized by Google

great extent be formed as to the probability of return of the disease in other glands, or the increase or subsidence of small deep glands that may have been left by the condition and progress of the scar. Ugly scars may be removed and the patient's appearance greatly improved, but the cause must at the same time be taken away or the result will be disappointing. The question of early or late removal is a very important one, and can only be answered by the consideration of the special features of each particular case. As a rule, there are decided advantages attending early removal. In the early stages the glands are as a rule more movable and more easily taken away; there is also to be borne in mind, as indicating early removal, the important fact that an infected gland constantly tends to infect others, and is a source of danger so long as it remains; glands too, if left, will often break down, capsule giving way, and discharge, not externally through the skin, but into the cellular tissue of the neck, causing burrowing sinuses and extension generally of the disease. On the other hand, removal whilst the disease is in an early and progressive stage is more likely to be followed by a return than is removal when the disease is in an arrested and quiescent condition. And, *cæteris paribus*, the younger the child the more likely is the disease to recur. No general rule can be given, but each case must be taken on its merits. If the constitutional disturbance set up by the glands is sufficient to maintain increase of temperature, it is better to operate. Of course, the constitutional condition and the local trouble act and react on each other, but generally an indication for action or delay can be got at by deciding as to whether it is chiefly the constitutional condition which, in addition to perhaps local causes, is developing and maintaining the gland trouble; or whether this gland disease, having been started by combined local and constitutional causes, is now in itself injuriously affecting and deteriorating the health. In many of my patients the latter has undoubtedly been the case, and I have numerous charts showing the temperature, which has ranged from 100° to 103° F., dropping to normal shortly after removal, with a corresponding improvement in the general health. But in many cases there are distinct benefits to be obtained by waiting. The glands will not altogether return to their normal condition and size, but they may become smaller, surrounding inflammatory deposits may be absorbed, adhesions may be set free, loosened, or stretched, general health may be improved, and a more favourable state of the patient, both locally and generally, be brought about. The social position of the patient must also influence our action. In the case of a poor child, residence at the seaside, except for a limited period in a hospital, is unattainable, and time is of importance. The well-to-do classes, on the other hand, are averse to submit to operation until less decisive measures have been first tried. Finally, I would say wait, if possible, to establish general health and get disease quiet.

I cannot help thinking that excision of scrofulous glands is an operation which rests on sound surgical principles. We have a diseased, an irreparably diseased, condition in organs which the body can well spare—a condition which tends constantly to cause infection by continuity of adjoining glands, and even by means of the blood, to develop tuberculous disease in distant parts. Why should this diseased product be allowed to remain to work its own sweet will unmolested and undisturbed? Tuberculous disease is removed from all other accessible parts or organs; why should glands be privileged? I submit there is every reason why they should be removed, and removed thoroughly. Take the case of a family of scrofulous tendencies. One member only may actually develop the disease, say, in the form of scrofulous glands; if this child's diseased glands are thoroughly removed, if all sources of irritation are removed and the child's health established by being sent to the seaside, that child is put back in the position of his brothers and sisters who have never had the disease. He is not more likely to have a return of the scrofulous glands than his brothers and sisters are to develop them—in fact, he is cured. The only valid argument that could be used against the excision of scrofulous glands is the possibility of undue risk. Scrofulous glands are situated usually in the midst of important vessels and structures, and their removal might be considered dangerous. I can only state that I have excised scrofulous glands for many years, and that I have never lost a case. I attribute this success partly to good fortune, but mainly to the fact that I never incur, by premature closing of the wound, the slightest risk of retention of discharges or bagging. I have operated on many cases of great enlargement. I have removed more than a pound's weight in glands from one patient, and more than one hundred in number from another. I have excised glands in a case where the mass was sufficiently large to threaten suffocation. My colleagues are doing the same, and we can prove, by a great number of cases, that the operation is not attended with undue risk, and that the results are good.

Margate.

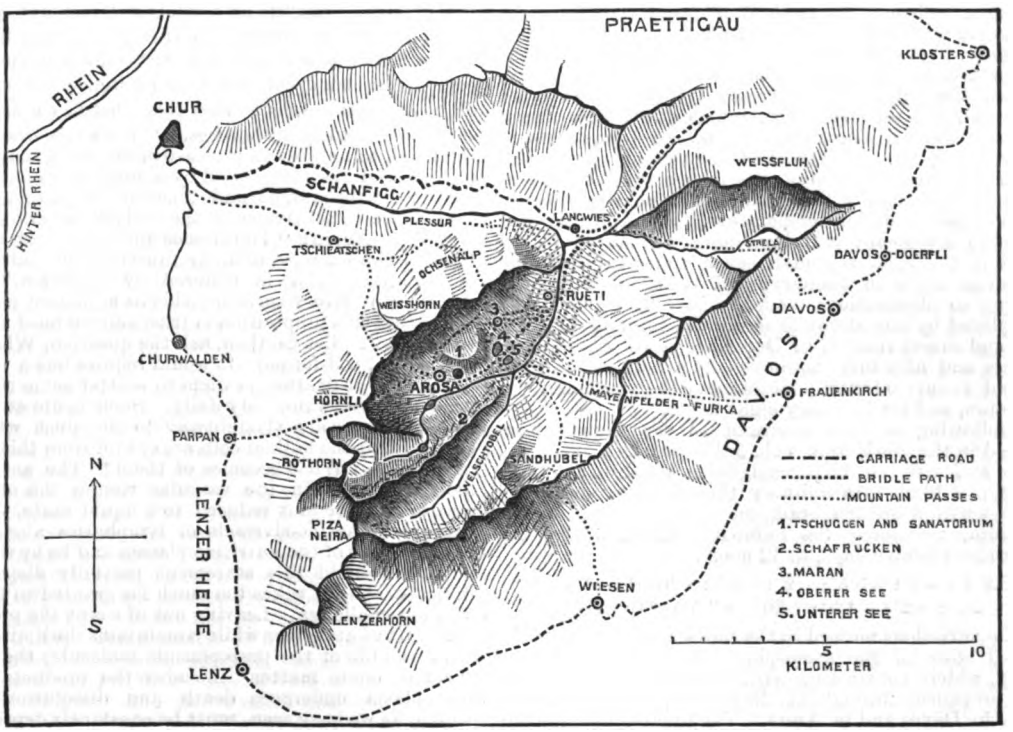
AROSA AS AN ALPINE HEALTH RESORT.[1]

BY WM. EWART, M.D., F.R.C.P.,

PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN; LATE ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

AFTER five successive winter visits to the Alps, I am more than ever of opinion that time is working in favour of the Alpine treatment of phthisis. The natural repugnance of most patients to the idea of a glacial winter, and a wise diffidence on the part of the profession, have checked for a long time its wider application; but the delay has been of use as a means of testing its value and of confirming its ultimate success. We now more fully realise that, if phthisis is to be cured by residence in the Alps, the fleeting opportunity must be seized *early;* this circumstance alone has led, during the past few years, to a progressive increase in the size of the winter colony. Moreover, in addition to consumptives, many have found their way to the Alps in whom pulmonary disease was merely *threatened.* And, lastly, the remarkable results obtained in the treatment of early phthisis have awakened most physicians to the capabilities of the Alpine cure in a larger class of cases presenting in common the feature of depressed vitality. Nevertheless, for a considerable number of patients the length and the hardships of the journey to the high Alps have hitherto been an insuperable objection. The winter journey to the Engadine is likely for some years to retain its romantic and adventurous features. But to Davos a railway is already partly laid; this winter it will have reached Klosters, leaving but ninety minutes instead of seven weary hours of diligence journey; and in the following autumn Davos will possess its own terminus, and will doubtless welcome a vastly increased number of visitors, both invalid and healthy. From that day the charm of an Alpine winter holiday will cease to be the secret of the few; and it may safely be predicted that Davos will become the great centre in the High Alps, not for patients only, but for lovers of mountain climbing, of skating, and of the toboggan. On the other hand, instead of being as heretofore an *Ultima Thule*, Davos will henceforth provide ready access to other favoured spots, and residence in the altitudes will admit of greater variety than in the past. Foremost among the members of the Davos group of health resorts must be mentioned Wiesen and Arosa, each differing from the other and from Davos in its climatic virtues, and each excelling in its own special variety. Wiesen has already for several years subsisted as a satellite of Davos, but although it has been brought to notice by the writings of Dr. Tucker Wise, it has not yet achieved the development for which its beautiful climate, and its yet more beautiful scenery, afford secure pledges. Arosa, though later in the field, is likely to equal the fame of its predecessors. Hitherto, but for a paper by Dr. Fritz Egger in the *Correspondenz Blatt für Schweizer Aerzte* for 1886, it is unknown to medical literature. The brief account which follows may therefore present some interest, especially since, through the kindness of Dr. Egger and of Dr. Herwig (the former practising and the latter residing in Arosa), I am able to supplement my own observations with some of the local knowledge acquired by old residents.

Upwards of 400 years ago a handful of adventurous Davoser shepherds crossed the mountains which form the western boundary of the valley of Davos, and founded in the smaller and more elevated neighbouring valley a village, to which they gave the name of Erosen. The new



[1] Written at Arosa in February, and communicated in March of the present year.

Digitized by Google

settlement remained for a long period within the jurisdiction of Davos; and to the present day a vestige of the former allegiance survives in connexion with the administration of relief to the poor. The colony never acquired any great size; but with the ill-advised sale to the city of Chur of the richest of its woods and of its grazing-alps, it entered upon a long period of decline. Two years ago its permanent population had dwindled to fifty. But Arosa was destined to be colonised once more from Davos, not as formerly with sturdy mountaineers attracted by the fragrance of its pastures, but with patients anxious for a winter shelter under its snow-clad mountains. The fresh immigration was headed, six years ago, by Dr. Herwig, and two years later by Dr. Egger. During the winter 1887–8, in scattered array, a total of eleven visitors were content to put up with primitive accommodation. But, with the onset of the next winter, Arosa, long treasured by the Swiss as a delightful summer refuge, almost untrodden by the foreign tourist, long foretold by experts as the winter station of the future, suddenly sprang into existence as an

MAP OF AROSA,

WITH AN INDICATION OF ITS RELATIONS TO THE DAVOS GROUP.

N.B. The scale of measurement is applicable only to the Valley of Arosa, not to the surroundings, which are merely indicated, without reference to distance.

Alpine health resort. The sanatorium, built by Dr. Herwig during the spring and summer of 1888 for the accommodation of thirty patients, was invaded, even before its completion, by visitors unable to find room in any of the six summer hotels; and during its first winter it has been occupied by twenty-four residents. The patients, mostly German, but including two English ladies, a Belgian, and, strange to say, a Frenchman, have enjoyed the undivided run of this lovely valley, free to toboggan down its long slopes, free to roam on snow-shoes, fearless of the *landjäger*, over its hills, meadows and hurdles, and to exchange distant *jodels* through stillness yet undisturbed by any strange voices; but at times the saddening thought has occurred to them that the same monopoly of privileges will never be theirs again.

The natural advantages of the valley of Arosa are probably unsurpassed. An oblong amphitheatre of mountains surrounds the valley on all sides, except at the north-east corner where the Plessur stream escapes with a sharp bend, between densely wooded hills, into the Schanfigg Thal. This break in the investing heights is guarded by the Weissfluhe; and from this mountain to the Piza Neira a continuous chain separates the Prättigau and the Davos Valley from the district of Arosa. Between the latter and Wiesen intervene the Sandhübel Mountain, the gorge of the Welschtobel and the ridge of the Schafsrücken. The higher or southern part of the valley is included between this ridge and the Weisshorn; whilst into the northern half opens the Welschtobel. The valley is parallel with the valley of Davos and slopes from S.W. to N.E. Its shape would be a perfect oval but for the protrusion, half-way across it, of a small semicircular mountain, the Tschuggen, which renders it roughly kidney-shaped, and divides it into a northern and a southern half. The latter contains, in descending tiers, the elevated Aelpli-see; the Schwelli-see, also of considerable altitude; and the hamlet of Arosa. This is, strictly speaking, the Arosa Valley as opposed to the See-grube on the other side of the Tschuggen. The complete absence of trees and the huge snow-slopes into which it gradually rises impart in winter to this end of the valley a wild arctic aspect.

The sanatorium is built half-way down the southward slope of the Tschuggen, at an elevation of about 6200 ft., near the upper limit of the pine-tree woods, which extend from this point northwards as far as the end of the valley, clothing its bottom and its opposite slopes, and leaving in the See-grube an open surface of tolerably level ground around the two lakes, known as the Unter-see and the Ober-see. The sanatorium, absolutely sheltered from the north wind, is open to the Föhn, which seldom blows, and is taken in flank by the milder touch of the Heiterluft (fine weather air) or west valley wind, which descends every day, across Arosa, from the Hörnli. It faces due south, and receives, in addition to the direct sun rays, much reflected heat from the snow-clad Schafsrücken; it also enjoys a fine view over the picturesque snow-tipped woodland scenery to the north, which contrasts pleasantly with the desolate landscape to the south. From the narrow gully contained between the foot of the Tschuggen and that of the Schafsrücken the valley broadens out northwards into the See-grube, which has a mean elevation of 5800 feet. Here the protection from wind, although not absolute, is as good as need be desired, and I am told by winter residents that during the heavy Föhn-storms the woods afforded a perfectly

Digitized by Google

still retreat. On the shores of the Ober-see and of the Unter-see I noticed lovely sites, two of which are already reserved for large buildings. Hitherto valley mists, so common in the still valleys, are almost unknown, even in the See-grube.

Arosa offers ample opportunities for out-door *exercise*. A long level walk extends through the woods to Maran; the other walks are more or less steep, and their choice is limited in winter. Fortunately snow-shoes, almost unknown at Davos and St. Moritz, are here in constant use and have rendered the patients independent of the few bridle-paths with which the natives are satisfied. With their help some of the stronger invalids have ascended the Weisshorn, and even the Rothhorn, and have visited most of the passes. The hill sides are singularly well adapted for the use of the toboggan, and some excellent skating was enjoyed on the lower lakes before the heavy snow-falls. Meanwhile, patients unfit for exercise recline in the sun under rugs or eider-down pillows on the balconies or in the verandah.

The meteorological observations which have hitherto been collected entirely confirm the inference that Arosa is typically a serene altitude. Absolute stillness, which is not an unmixed boon, does not exist here. The *Heiterluft* provides daily for a sufficient renewal of air, and the See-grube possesses an additional air-current passing from the valley of Langwies to the Welschtobel. As to the quality of the air, after a circular journey from Davos to the Engadine, and from the Engadine to Arosa, I found here rather more stimulation than at Davos, and decidedly less stimulation than in the Engadine. As far as I was able to compare notes, the oscillations of the weather were practically the same here during the month of February as at Davos. Although a thousand feet higher than Davos, Arosa possesses a milder temperature. The following fact requires no comment: mid-day dinner was served to the patients in the open verandah seven times in December last, eleven times in January, and twice in February. According to observations made by Mr. P. Haenel, and kindly placed by him at my disposal, the interval between sunrise and sunset reached in December last a minimum of five hours and fifty-three minutes and a maximum of six hours and twenty minutes; for January the maximum was seven hours, and for February eight hours.

The following are the averages of the temperatures registered in the *shade* from Feb. 3rd to the 14th inclusive. Average at 7 A.M.: − 11·7° centigrade; at 1 P.M.: − 7·7°; at 9 P.M.: − 10·3°. An ordinary thermometer, suspended in contact with a wooden beam, on the *sunny* side of the sanatorium, registered the following values during the same series of twelve days, at 12 noon:

+12·5°; −2°; −3·5°; −2°; +22°; +31·5°; −1·5°; +2·7°; −2°; +1·5°; +20°; +3·5° centigrade.

The wide variations noticed in the series are evidence of the unsettled state of the atmosphere during the period in question, widely contrasting with the steady fine weather which prevailed throughout November, December, and January in Davos and in Arosa. The highest temperature registered by the same instrument in December was +34·5° centigrade. The lowest temperature registered in the shade (at 7 A.M. and at 9 P.M.) was −20° centigrade. Although these various observations were not made with protected thermometers, they afford a rough idea of the variations in temperature to which are exposed winter residents in the altitudes, and which the dryness of the air enables them to tolerate without discomfort.

In conclusion, Arosa, the latest addition to the list of Alpine resorts, bids fair to be one of the best; and we may well wonder that so eligible a spot should have been hitherto overlooked. The mountains by which it is so remarkably sheltered have placed it beyond the reach of most invalids. To the present day, Arosa possesses the charm of being accessible only to foot passengers; in winter, by a single path, from Langwies, a stiff walk of from two hours and a half to three hours; but in summer by six mountain passes in addition. A carriage road is, however, in course of construction, and before next winter it will be possible to cover the whole distance from Chur in four hours and a half. Perhaps also before then ample accommodation will have been prepared for a larger winter colony. As regards the sanatorium, the success already achieved among a German *clientèle*, under the able management of Frl. Herwig, renders it more than doubtful whether any room will be left next winter under its roof for the reception of English visitors. But if any should make the attempt to partake of its hospitality, they should come prepared to find themselves in the minority.

Curzon-street, W.

AN ESSAY ON THE

FUNCTIONS OF INDIFFERENT CELLS IN THE HUMAN ORGANISM.

BY JAMES DICKINSON.

(Concluded from page 636.)

THE normal occurrence of the migration of leucocytes must be considered as established. What do they do when they have migrated? Is there in the body any small but constant deposit of cell débris (such as results copiously from an injury) demanding bodily removal, and providing just such a task as the wandering cells in the tissues are competent to perform? It seems extremely likely that there is this deposit. The life of a cell is not in point of duration that of the organism of which it is but a tiny item. It is believed that each cell lives its little life and dies while the complex organism continues its existence. The analogy of all communities tells us that this must be so, and that it is so is recognised by authorities. "We know that an epithelium cell, as notably in the case of the skin, may be bodily cast off and its place filled by a new cell, and probably a similar disappearance and renewal of histological units take place in all tissues of the body to a variable extent." (Foster.) Again: "The tissues and organs of the animal body in the exercise of their functions are subject to loss of material which is restored by nutrition." (Quain's Anatomy.) Every surface yields us abundant material evidence that this proposition is true, and we need not hesitate to accept it. Let us, then, ask the question, What becomes of the dead cell-forms? It would require but a very minute percentage of deaths per diem to scatter some thousands of dead cells about the body daily. Such as die at the surface are free to return straightway to the dust whence they sprang. But the bulk of cells are cut off from this easy mode of disposal. What becomes of them? The authority last quoted says: "In the vascular tissues the old or effete matter must be first reduced to a liquid state, then find its way into the bloodvessels or lymphatics along with the residual part of the nutritive plasma and be by them carried off." No doubt this statement partially disposes of the difficulty, but it takes too much for granted to be accepted without challenge. Leaving out of count the products discharged by katabolism while it maintains the limits consistent with the life of the protoplasmic molecule, the expression "old or effete matter" includes the products left when protoplasm undergoes death and dissolution—products which, as we have seen, must be constantly deposited in the tissue. Now, in the statement just quoted all these products are assumed to be soluble in the lymph stream. But one of the products freed by the natural dissolution of protoplasm is fat, as is seen when a mass of protoplasm cut off from its blood-supply undergoes fatty degeneration. What happens is broadly this. The complex molecule of protoplasm, in the absence of material wherewith to carry on its constructive changes, continues its destructive changes uncompensated till it is fairly broken up into less complicated but more stable molecules, some of which are fatty. We see the same thing in the tissue degenerations of old age, when the machine is nearly run down and destructive metabolism generally is gaining the upper hand of constructive. It is by so carrying its destructive metabolism too far that one conceives all protoplasm ultimately dies, if left to die in the course of nature, a point being at last reached at which no reconstruction is possible and the molecule breaks up into stable residues. It is most probable that all forms of the protoplastic molecule contain, in addition to a proteid basis, fatty and carbohydrate residues. The combination may be in different proportions in different forms, but probably all forms on undergoing natural dissolution yield residues representing these three classes of substances. At all events the facts shew that a fatty residue is almost invariably a product of

Digitized by Google

this dissolution. Some forms of protoplasm by natural dissolution yield it in considerable quantity. Nerve tissue especially leaves an abundant fatty residue. Native protoplasm is also highly productive of the same substance, as is seen in a caseating abscess when migrated leucocytes are dying of starvation. Muscle and gland protoplasm leave no inconsiderable fatty residue. But fat is in water the fluid basis of lymph, an eminently insoluble substance. A view that requires all effete products to undergo solution before they can be removed is therefore inadequate to account for the disposal of at least one of those effete products. But this view undoubtedly affords a partial explanation of the means whereby disintegrated protoplasm is removed from the tissues. We know that there are found in all tissues certain nitrogenous crystalline bodies, amongst which kreatin is the most conspicuous. Since they are such bodies as would readily be carried away by the lymph-stream, yet are always present, we infer that they are constantly being formed and as constantly being converted into other bodies and carried away (Foster). These bodies have been called the "wear and tear" products of metabolism. But in the metabolism of protoplasm two processes must be distinguished—*change*, which is anabolism and katabolism within the limits of life, and *death*, which is katabolism beyond recovery. It is probable that the former process gives rise to little or no nitrogenous waste, and it is the latter process to which we must look as the chief source of extractives. In fact, of the three residues which I venture to assume are liberated by the final katabolism of protoplasm, extractives represent the proteid residue. These substances are no doubt taken up by the lymph-stream in which they lie, and so find their way through the lymphatic channels to the blood, and thus to the nitrogen-excreting organs. If any portions are yet available as nutriment, they would take their place among the other foods held in the plasma. But just as constantly as extractives there are found in all tissues—leaving out of count those in which they are special features—substances belonging to the two classes, fats and carbohydrates. This is what we should expect in the light of the foregoing considerations, and the obvious conclusion is that these substances have a source identical with that of the extractives, and that all three represent residues left by that final splitting up which ends the katabolism of the molecule of protoplasm. The carbohydrate residue takes the form of glycogen. Neither fat nor glycogen can be said to be substances which would readily be taken up by the lymph-stream. Glycogen, indeed, is just that less soluble form which carbohydrate assumes (e.g., in the liver) in order, probably, that it may *not* be carried off by the lymph-stream. But if the view be correct that fat and glycogen are constantly though in small quantities deposited in the tissues by the natural death of cells, and if the lymph-stream is inadequate to the effectual removal of such substances, must there not exist some other agency by means of which they may be constantly swept from the tissues and prevented from accumulating? Does not this look like a need such as leucocytes are just qualified to supply—a need more diffused and less intense, but of precisely the same nature as the need we found them supplying in inflammation?

It is established that the migration of leucocytes from the bloodvessels into the tissues is a normal occurrence. It has been shown that it is at least highly probable that there is work for them to perform in the tissues such as is within their powers, and such as we have seen them performing under certain conditions. Have we any certain evidence that they do perform this work? We have. The microscope shows that the protoplasm of leucocytes has always embedded in it granules of various sizes, which irresistibly suggest themselves as prizes picked up and undergoing the process of intracellular digestion. It is, indeed, the presence of these granules that enables observers to distinguish leucocytes among other cells. But what seems to finally establish the soundness of the considerations above given is the fact that most authorities describe these particles as consisting of fat and of glycogen. This is just what, on the foregoing grounds, we should prophesy, and what we should look for with trepidation as a crucial test.

To sum up the results so far obtained. Inflammation, then, is a process to which, in a very mild form, the whole body is subject all its life. It is a cleaning-up process. Leucocytes are the scavengers of the body. Just as their structure and organisation are on the lowliest type, so the work they do is the most menial, though of utmost moment to the body at large. The primitive freedom which they alone retain is, naturally enough, the very thing that makes them of use to their fellows in the community that have resigned it in pursuit of special powers. With all their freedom their life is not their own, but belongs to their community. Their voracious and indiscriminate appetites are utilised in the plan of the body to supply important needs. In the alimentary and respiratory tracts there are special needs which leucocytes supply. Throughout the body is probably a constant and general need of their services as scavengers, a need created by the natural death of individual cells. Among the products of this death is a nitrogenous residue which is removed mainly, perhaps wholly, without their help. But there are also fatty and carbohydrate residues, and leucocytes are concerned in the removal of these. In effecting this removal, they utilise as nutriment all that is yet available of the débris. The tissues are held in constant survey by a procession of leucocytes which are distributed by the bloodvessels, escape thence through the walls, and, traversing the interstices of the tissues, stray ultimately into the proper lymphatic channels, where we will follow them for the present only as far as the first lymphatic gland they chance to meet. Ordinarily the escape from the bloodvessels is not a conspicuous event, but in cases of urgent need it is favoured by some change in the wall which has been called "molecular." Into the blood-channels fresh relays are poured from the lymphatics through the communication in the neck—continuously poured, but with especial vigour during the time absorption at the lacteals is most active. Thus, leucocytes being necessary to all parts of the body, follow precisely the course of circulation taken by the nutritive plasma.

But the physiology of indifferent cells in the human body is not yet fully outlined, for the question next arises, What is the function of the so-called lymphatic glands, which consist chiefly of amœboid elements? Keeping in mind the work of sweeping all débris from the body, it is not difficult to discover a probable use for these organs. For though the sluggish lymph-stream is obviously inadequate to sweep through the interstices of the tissues particles such as are seen in the bodies of leucocytes, it is quite conceivable that particles in a more minute state of division might be so carried off, suspended, without being in solution. Moreover, it seems not unlikely that in the breaking down of a cell structure a fine detritus would be loosened into the plasma. Grant that this be so. Then if it go on unchecked it must end in completely vitiating the plasma as a means of nourishment. It would in fact go on accumulating till it choked the vessels. For no cells could deal with it except such as retain to some extent the amœboid power. The use of the amœboid power is to enable a cell to pick up particles. If it is to become a highly specialised cell, the necessity of picking up food by its own activity must be obviated by its being provided with food in a soluble form. It cannot give up its amœboid powers unless this difficulty be arranged for it. And so we find it in the body where the bulk of cells take up their food or whatever products their functions are concerned with, in a form the assimilation of which calls for no more than a chemically selective action on their part. Leucocytes and some other cells that possess limited amœboid powers are the striking exceptions. Thus we never find particles in a muscle cell unless they be the products of its own degeneration. Supposing, then, a fine detritus to be constantly discharged into the plasma, it would, unless it were removed by special means, go on accumulating, and work two disastrous effects. It would, in the first place, displace useful (because soluble) nutriment; and, in the second place, it would render the flow of plasma through the tissues increasingly sluggish. Starvation of all highly specialised cells would be the climax. Obviously the efficiency of the plasma as a supplier of nourishment to the tissues depends, for one thing, on its being kept clear of suspended matter. The clearer it is the more freely will it permeate the tissues and penetrate into the protoplasm of the cells. If, as seems likely, there is a constant discharge of fine detritus into the plasma, there must be some efficient filtering apparatus constantly at work to clear it away. There are organs which filter the

Digitized by Google

blood in a chemical sense, but none have yet been recognised as engaged in a mechanical filtration of suspended particles from either blood or lymph. Yet a lymphatic gland is constructed so as to suggest a filtering apparatus. It may be briefly and diagrammatically described as a dilatation in the course of a lymphatic channel occupied by a fine reticulum, the meshes of which serve to support a loose crowd of leucocytes. The leucocytes, loose only in the sense that they are free, are crowded densely, and through the crowd all lymph has to flow in order to pass from the afferent to the efferent vessel. It would be a miracle if the minutest particle of suspended matter brought by the afferent ever reached the efferent vessel through such a phalanx of phagocytes. The apparatus is calculated to maintain the most rigorous filtration, and probably all lymph on its way from the tissues has to pass through one or more such organs before it is redistributed by the blood-channels. If lymphatic glands have the function here suggested their work is complemental to that of the isolated errant cells that scour the body, and pick up all débris that is too bulky to be carried away by the plasma. We see how naturally errant leucocytes brought by the afferent vessel would take their place among those entangled in the meshes of the reticulum, to join in a work which is but a continuation of their own. We see how other leucocytes would escape on the efferent side of the gland with the lymph, to be carried a stage nearer the portal through which they would ultimately be admitted into the blood-stream; here to begin a new phase of existence as independent leucocytes till brought round once more to the afferent side of the lymphatic gland system. It must be added that lymphatic glands are probably among the chief seats of reproduction of leucocytes, the comparatively inactive life leucocytes lead in these situations being most favourable to that function.

There still remain for consideration certain aggregations of amœboid cells that cannot be classed either with lymphatic glands proper or with those lymphatic masses which, distributed along the respiratory and alimentary tracts, guard the natural gateways of the body. I refer to those aggregations of amœboid cells seen in the spleen and in the red marrow of bone. There can be no manner of doubt that the functions of both these tissues have relation to the red corpuscles. For just as lymph—i.e., plasma without red corpuscles—is discharged freely into the substance of lymphatic glands, so blood—i.e., plasma *plus* red corpuscles—is discharged freely into the substance of the spleen and of the red marrow. By contrast of these relations the inference arises that the spleen and marrow concern themselves with precisely that element that makes the difference between lymph and blood. Observation amply confirms this *a priori* deduction, though we are at present unable to say positively whether the two tissues are identical, or, as seems more probable, complemental in function. Again, we should, on *a priori* grounds, look naturally to leucocytes to provide new red cells and to dispose of old ones, the former corresponding with their organising, the latter with their absorbing, powers. But the final word on this matter has yet to be said, and the exact relations of the spleen and red marrow to the red cells and to each other have yet to be worked out. The elements found in circulating blood that have been described as transitional between leucocytes and red cells are probably leucocytes that have taken into their bodies the disintegrated remains of red cells. Whether such leucocytes do afterwards undergo any transformation has yet to be determined. Lastly, as a function of leucocytes, reference must just be made to the power of organisation which they display under certain conditions. This function concerns chiefly the earliest stages of the organism's development, and in the fully developed organism falls naturally into abeyance until a need for it arises in the shape of destruction of tissue.

Such are the functions of indifferent cells in the human body. These elements can no longer be looked upon as insignificant and useless or harmful. When it is remembered that their functions serve such varied uses as food absorption, antiseptic protection, regeneration, and, most menial, but not least important, the sweeping up of débris, it must be admitted that they are as indispensable to the well-being and continuance of the organism as are the elements of any tissue that has received distinct recognition.

Bridge-road, N.W.

TWO CASES OF

NECROSIS OF THE ALVEOLAR PROCESSES FOLLOWING MEASLES.

BY R. CLEMENT LUCAS, B.S. LOND., F.R.C.S.,
SURGEON TO GUY'S HOSPITAL AND TO THE EVELINA HOSPITAL FOR CHILDREN.

THE cases of acute disease which are treated by physicians not unfrequently leave local weaknesses and degenerate tendencies, which fall, perhaps months afterwards, to the charge of the surgeon. These local affections may in many cases be regarded as direct sequelæ of the acute disease, and particular exanthemata seem prone to produce necrosis in particular situations. The rib necrosis and tibial nodes which may follow typhoid fever are not, so far as I am aware, often found as a result of measles or scarlet fever, nor do I know of any case of typhoid fever which resulted in exfoliation of the alveolar processes of the jaws. The following two cases of alveolar necrosis presenting characters so very similar and resulting in each case from the same cause, I have thought well to place on record together. It is curious also that the two children were of the same age.

J. B——, aged three, was admitted into Guy's Hospital, under my care, on July 31st, 1889, and the report is from notes taken by Mr. Sydney T. Roberts. There was a healthy family history. Five weeks before admission the child suffered from measles and inflammation of the lungs. He was much convulsed during the attack. The illness lasted about a fortnight, but the mother noticed after his recovery that there was something wrong about his mouth. When admitted the child had a fairly healthy appearance. There was a little breaking out about his lips, his mouth was very foul, and the breath extremely fetid. On the front of both the upper and lower maxillæ, and limited to the anterior or central parts of both alveoli, was a greenish-black portion of necrosed bone. That on the upper jaw was quite loose, whilst that on the lower appeared still firmly attached. The disease appeared confined to the alveolar processes. The four incisor teeth had dropped out from the necrosed process of the upper jaw. In the lower jaw the necrosis, besides involving all the incisor sockets, included those of the two canines. On July 2nd, the patient being placed under chloroform, I removed with forceps the necrosed portion of the upper jaw. It came away with great ease. There was more difficulty with the alveolus of the lower jaw, and it became necessary to use a stronger forceps. The piece removed from the upper jaw was nearly quadrilateral, measuring three-quarters of an inch both vertically and transversely, and it contained the sockets of the four incisor teeth. The portion removed from the lower jaw was rather larger. It contained all the incisor sockets, together with half the socket of the canine tooth of the right side, and the whole socket of the corresponding tooth on the left side. The mouth was well washed out with Condy's fluid, and iodoform applied. On July 3rd the patient's mouth was in a much healthier condition, and the fetor much diminished. On the 5th the patient's general health was improved, and the condition of the mouth much sweeter. On the 7th the patient was discharged convalescent.

The second case I take from my Evelina Hospital notes. It is also a case of necrosis of both alveolar processes following measles, but the destruction was of an even more extensive character. By a curious coincidence the initials of the two children are the same, a fact which I mention lest it should be thought there was any confusion in the cases, but the sexes are different.

J. B——, aged three, was brought to the Evelina Hospital on Feb. 28th, 1883. The mother had died of some throat affection eighteen months before. The child took measles in August, 1882, and was ill for six weeks. After this it was noticed that her breath became very offensive. Shortly before being brought to the hospital the alveolar process of the upper jaw, corresponding to the four incisor teeth, dropped out. It was at the same time noticed that the alveolar process of the lower jaw was black and denuded of gum, whilst the breath remained very offensive. She was ordered a disinfectant lotion to rinse the mouth with, and cod-liver oil and steel wine internally. On March 7th, 1883, I removed with forceps the alveolar process of the lower jaw correspond-

Digitized by Google

ng to the four incisor sockets and the right canine, and afterwards the alveolar process of the upper jaw bearing the sockets of the molar teeth of the left side. The patient afterwards rapidly recovered, the gum surface granulating over.

It will be noticed that the necrosed portion of the upper jaw separated in each case earlier than that of the lower—a circumstance to be explained by the different texture of the two maxillæ, the lower being much stouter, heavier, and more compact.

Abstracts
OF
INTRODUCTORY LECTURES ETC.
DELIVERED AT THE
MEDICAL SCHOOLS OF LONDON
AT THE
Opening of the Session 1889-90.

KING'S COLLEGE.

INTRODUCTORY ADDRESS BY SIR ALBERT ROLLIT.

SIR ALBERT ROLLIT said the further men receded from their own school days the greater was the interest they took in the education of others than themselves. He had, therefore, responded to the request of the Principal and Medical Board to distribute the prizes, which was easy, and to address the students, which was difficult, especially those students of whom Carlyle spoke when he said, "I never knew a really clever youth who came of entirely stupid people." Education in London was in a period of transition. The great questions of metropolitan university, higher technical, and commercial education were either in the furnace or upon the anvil of public discussion. All were agreed that the present condition of university matters in the metropolis was unsatisfactory and inadequate, and it was certain that very soon either the University of London must meet the requirements of students and their teachers, or that a new teaching university would be founded, with King's and University as its chief colleges. Moreover, the London M.D. degree had been, from a professional point of view, almost unattainable, and hence an exodus of students took place from London towards other universities. This seemed, indeed, to be a practical and admitted evil, and it would be necessary to place within more reasonable reach a degree which it was now the custom to seek, and which should certainly not be severed from the professional advantages of the metropolis. It was to be hoped, however, that the present honour of the London M.D. and M.B. degrees would not be lost to the profession or their standard unduly lowered; and he suggested that the difficulty might be met by conferring the Doctorate of Medicine, as at Bonn and some other foreign universities, not only as a pass degree, but also as an index of higher qualifications, either *cum laude* or *cum multâ laude*, which was equivalent to honours. And if the proper requirements of a teaching university should not be met by the University of London, and a new one should be founded, let them hope it would be a true University—a school of universal learning, not an institution bearing as its name any such contradiction in terms as the proposed medical or legal universities. For this would not only narrow the course of professional instruction, but introduce into this country the evils of educational competition based on lowered standards and requirements, and followed by diminished reputation—a danger not unlikely to arise from the multiplication of collegiate universities. Having spoken of the English hospital system, and contrasted it with that of other countries, and having referred to the public services of the medical profession, Sir Albert discussed the subject of professional education. Owing to the mass of modern knowledge, the industrial principle, which was being applied in King's College and elsewhere, must, he said, also be applied to those intended for professional pursuits. As there was to be training for trade, so must there be preparation for a profession. Valuable as was classical culture, German was both disciplinary and of service in science, and it was dawning upon men that it might be possible not to be able to set Latin verses and yet to set a leg. He made an urgent plea for the professional, and also the general, study of psychology. For want of this, men, as a rule, ate too much, drank too much, slept too much, and fed and clothed themselves without much regard to their wants. If more adopted Sydney Smith's own prescription, "We cultivate literature on a little oatmeal;" if some dyspeptics appreciated the value of fish on a Friday, and any other day, of exercise on most, and relaxation on some days, such a reasoned and reasonable self-regard, call it selfishness if they chose, would at least mitigate disease, reduce the death-rate by half, and extirpate very much of the sum of human misery. Instead of this, however, the constant cry was that of the impenitent offender, "Oh, Lord, convert me, but not to-day," and so, in dyspepsia, &c., man continued to reap the reward of a guilty stomach. Again, physic and physics were closely connected, both etymologically and practically, and the medical man should therefore be more familiar than some were with the resources of natural science, and of the great physical instruments. To help nature, men must first know nature; otherwise they trust to chance and luck, and call it nature. He was glad, therefore, that physiological physics were prominently taugh at King's College, and a frequent educational defect thus remedied. But, after early education came the lifetime, and their profession offered perhaps the most noble of all careers; while what had been accomplished gave assurance of what was still to do. The world owed to the profession conservative surgery, the antiseptic principle, anæsthetics, and other life and limb saving inventions. The treatment of the insane had also been modified under the influence of such chairs as that of Psychological Medicine, while in the wide field of preventive medicine the labours of the profession had narrowed the kingdom of disease and death. But still the waste of human life was discreditably great, and in the national and civic duty of its reduction theirs would be the most powerful of all help towards that goal of health which society ought to seek and reach. This crusade was for Christ and His people, and the performance of public duty was the chivalry of to-day.

ST. MARY'S HOSPITAL.

INTRODUCTORY LECTURE BY DR. ROBERT MAGUIRE.

Protective Inoculation.

THE *rationale* of Protective Inoculation has been worked out only during the last ten years. In 1700 inoculation for small-pox was practised in Constantinople, and was introduced into England by Lady Mary Wortley Montagu. In 1768 Jenner began his researches on the protection afforded by cow-pox against small-pox. Possibly this was an instance of attenuation of virus by passage through animals of a different species. The more exact investigation commenced with the work of Pasteur on chicken cholera. The germ of this disease had already been discovered, but its relation to the disorder had not been fully worked out. To prove such a relationship it is necessary to show the constant presence of the germ in the subjects of the disease, to isolate the germ from its surroundings by cultivation upon suitable nutrient media, and finally to reproduce the disease by inoculating with such cultivations. The latter proof is wanting in the case of many germs because the lower animals are not always subject to the diseases of man, and the germ disease is too dangerous for an observer to submit himself to experiment. Pasteur applied all these methods to the germ of chicken cholera, and rendered certain its connexion with the disease. Methods of disinfection were then successfully practised, but these did not suffice to prevent further outbreaks of the disease. We can rarely control the action of germs when they are once introduced into the body. The cells of the body may fight the germs and even their spores, the germs may use up all their food and die of starvation, or they may commit suicide by poisoning themselves with their own productions; but medicines are almost useless to further these results. If full protection is desired, the body itself must be rendered incapable of being attacked by the germs. A former attack of the disease, from which the animal has recovered, affords in many cases the desired protection, and to attain this safely is the object of protective inoculation. Pasteur dwelt long upon Jenner's

Digitized by Google

discovery of cow-pox vaccine, and at last found that when cultivations of the germ of chicken cholera were allowed to remain exposed to the air for some time, they became incapable of causing the death of a fowl when inoculated; but such a fowl was then proof against the action of a stronger cultivation of the germ. This, Pasteur believed, was due to the action of the oxygen of the air, and he used this theory as a working hypothesis for his experiments on other diseases. Applying himself next to the splenic disease of cattle, the life history of whose germ had been worked out by Koch, Pasteur found that his method was rendered useless by the resistance of the spores of the parasite. These were not formed by the germ of chicken cholera. He observed, however, that at a temperature of 42° to 43° C., near the life-limit of the parasite, the spores were not formed, and then the rods of the germ, when exposed to the air, behaved like those of chicken cholera. Their virulence was diminished, but their vaccinating power remained. Experiments on a large scale were then conducted successfully at Melun in 1881. The researches of Pasteur were afterwards criticised. The vaccinating fluids were found to be not uniform in virulence, and consequently some animals were sacrificed by the process. The immunity was not everlasting, but this objection also applied to Jenner's vaccine. It was said that the immunity was only against the injected vaccine, and not against the acquired disease. But the results of inoculating large numbers of animals proved the value of the process. Other methods of attenuation were then discovered—namely, by heating the germ to 55° C. for ten minutes (Toussaint), by heating it to 47° C. for a longer time, and also by subjecting it to a pressure of eight atmospheres at a temperature of 38° to 39° C. (Chauveau), and by the action of antiseptics (Chamberland and Roux). Again, passage through various animals by inoculation was found to attenuate the virus of certain germs. The germs of chicken cholera and of swine plague were attenuated by passage through rabbits. The germ of sputum septicæmia could be attenuated by passage through guinea-pigs, and later on it was found that the poison of hydrophobia was weakened by being passed through a series of monkeys. Yet in all these cases the attenuated virus rendered an animal proof against the stronger poison. The virulence of these attenuated poisons could afterwards be restored by inoculating first young animals, and from them older ones, showing that the nature of the disease was unchanged. Possibly, Pasteur suggested, the oxygen of the air caused epidemics of infectious diseases to subside, while frequent passage of poisons through the lower animals brought about fresh outbreaks, or even produced new diseases. Pasteur's theory of attenuation by the action of oxygen had been much opposed. Chauveau found that when germs were heated to 47° C. attenuation was more rapid when the air was exhausted. Apparently, then, heat was the active agent. Pasteur had originally thought that he might have been dealing with two poisons, one weak, the other strong, the one counteracting the other. Other observers had found his inoculating fluids contaminated by foreign organisms, so this suggestion may really be true. In his later work on hydrophobia, he again remarked that other influences might be active in producing the attenuation. Yet he still used his first theory as a working hypothesis, and applied it to the investigation of hydrophobia, of which the germ has not yet been discovered. By infecting rabbits with the poison of this disease, he obtained a virus of uniform strength, situated principally in the nerves and spinal cord, and more powerful than that obtained directly from dogs. This could be attenuated by passage through monkeys, but the results were uncertain. By exposing the spinal cords of infected rabbits to dry, sterilised air, an attenuated poison could be obtained capable of protecting even man from the disease without endangering his life. Moreover, the period of incubation of the weakened virus was sufficiently short to enable it to produce immunity before the poison of a bite previously inflicted could become active. The value of this method is conclusively shown by the statistics most recently published by Dr. Ruffer. The lecturer pointed out to his student hearers, as the moral of his address, that they should not neglect the science of their studies, since it led to great practical results, and that, following the examples of the two observers chiefly mentioned, Pasteur and Koch, they should not be discouraged by difficulties, but always be working with such resources as they possessed.

ST. THOMAS'S HOSPITAL.

INTRODUCTORY ADDRESS BY MR. WILLIAM ANDERSON.

THE main subject of this address was a historical review of the growth of surgery in Europe from the beginning of the sixteenth century. After a brief reference to the rise of Greek surgery from the time of Hippocrates to the death of Paulus of Egina, and its transmission in a weakened form by the Arabs, a picture was drawn of an educated European surgeon of the close of the mediæval or conservative period. The chief items of his library and armamentarium were enumerated, and the nature, extent, and source of his professional lore explained. He was found greatly inferior in originality and practical attainments to his Greek predecessors; and, inheriting all the timidity of action of his Arab teachers, allowed the most important branches of his craft to fall into the clutches of a horde of quack bonesetters, stone and rupture cutters, cataract couchers, and the like, while the rivalry of a lower grade of surgeons in France, England, and Germany threatened his complete extinction. An account was then given of the origin and progress of the coming men, the barber-surgeons, and the endeavours on the part of their emancipated brethren in France and England, the military surgeons, to elevate their calling by the formation of associations such as the College of St. Côme in Paris and the Fellowship of Surgeons in London. A new era of surgery opened with the sixteenth century, owing partly to the revival of anatomical study under Berengarius, Vesalius, and others, partly to the necessity for a fresh departure in connexion with the rapidly prevailing use of firearms in warfare, and the invasion of Europe by syphilis. The substitution of clinical observation and pathological research for the study of books of past ages was strongly advocated, and the genius of a few men, almost unaided by the schools, exercised a wide influence upon surgical aims and practice. The chief advances during the period were in the rational treatment of gunshot wounds, the power of controlling hæmorrhage in amputations, and the relief of strangulated hernia; but beyond this a novel and unconventional type of surgical literature in the vulgar tongue played an important part in diffusing knowledge and stimulating inquiry. The services rendered by Ambroise Paré, Pierre Franco, and other representative surgeons of the period, were passed in review. The seventeenth century although illuminated by Harvey's discovery of the circulation of the blood, and the researches of Aselli and Pecquet upon the lymphatic vessels, produced no surgeons of the first order. The treatment of gunshot wounds, however, made considerable progress under Wiseman and Magati, and a few other steps of advance were taken. Surgical education remained in a low state except in Italy, where a system of clinical instruction was established. This long stagnation of surgical enterprise was succeeded in the eighteenth century by the manifestation of forces of a higher and more varied type. The scientific teaching of anatomy and surgery made great strides. Surgical pathology was created by the labours of Hunter, Petit, Pott, and others. Operative surgery attained a development that left nothing to be desired in the directions of boldness and manipulative skill. Important schools were founded in London, Paris, Berlin, Vienna, and Philadelphia; and the scientific and social position of the surgeon everywhere except in Italy, where it had always been high, underwent a great change for the better. The master spirit of the period was John Hunter, who first evolved the broad principles of surgery which were to direct all future research and practice. The present century was referred to as one of phenomenal progress in scientific and practical surgery, especially during the last three decades. The vast extension of professional education, the great development of the medical press, the facilities provided for investigation, and the multiplication of scientific appliances for diagnosis and treatment were commented upon, and the far-reaching effects of the two great surgical discoveries of the age—the means of annulling pain during operation, and the relations of germ infection to the progress of wounds—were discussed in detail. The address concluded with some remarks upon the lessons taught by the history of the evolution of surgery, and a few words of counsel to the portion of the audience just commencing their term of professional education.

UNIVERSITY COLLEGE.

INTRODUCTORY ADDRESS BY MR. RICKMAN J. GODLEE.

THE lecturer, in opening his address, deprecated the custom, which was becoming obsolete, of giving introductory addresses as being laborious to the giver and useless to the student. He then gave an account of an amputation performed in the sixteenth century by the distinguished French surgeon, Ambroise Paré, in order to show the crudities of knowledge and treatment at that period compared with the advanced state of surgical knowledge at the present day. Reference was then made to the state of surgical knowledge even so recently as twenty years ago, and, by way of illustration, an imaginary case of injury was given with the treatment which would have been accorded at that time. Mr. Godlee went on to show that his supposititious case would to-day not be subjected to amputation at all, but the patient would most certainly have his limb saved, such were the enormous strides that surgery had made in recent years. The importance of scrupulous surgical cleanliness in the performance of operations was strongly insisted upon. He congratulated them upon the improved tone which now prevailed, and which no longer made the term "medical student" one of reproach. He then referred to the great increase in the system of teaching by demonstrations, which he maintained was only of partial advantage; for whilst it no doubt increased the average attainments, it levelled down as well as up, and made the mere acquiring of a degree seem the one thing needful.

WESTMINSTER HOSPITAL.

INTRODUCTORY ADDRESS BY DR. PHINEAS T. ABRAHAM.

THE lecturer, after referring to the honour his colleagues had done him in entrusting to him the duty of opening the school, alluded to the gradual waning of these time-honoured annual meetings of teachers and students, and said some words in favour of such functions. In welcoming the new students, he said that he considered that they had done well in choosing the Westminster Hospital as their *alma mater*. Being a small school there was no fear of their being lost in a crowd, but coming, as they would do, into close contact with all their teachers they might command more personal assistance from them than would be possible, except for a favoured few, in the large schools. They would, moreover, reap the great advantage which the Westminster Hospital affords of an abundance of clinical material in proportion to the number of its students. The lecturer then referred to the great success of Westminster students at the various examining boards. In physiology no less than 83 per cent. had been successful. Examinations, however, were not everything; the teacher had to remember that a medical man had to be always learning, observing, and judging. Medicine was progressive. The student had to be equipped with methods of thought and research, as well as with principles and facts, which would be useful hereafter. The medical curriculum was in a great measure calculated to develop a man's faculties, and to train him to accurately see and interpret natural phenomena; but our system was not yet perfect. He considered that those who aspired to become members of a profession which should be pre-eminently scientific, and which should be second in culture to none in the land, should show evidence of a good general education—e.g., by passing a preliminary examination of the standard of the London matriculation and a substantial knowledge of chemistry and physics, the laws of which really govern all the phenomena of health and disease. The medical course should, in his opinion, be extended to at least five years; for while the subjects of professional education had multiplied and their range enormously extended, the time allotted to their study alone had not increased for many years. It might be objected that if the conditions were made so much more onerous the supply of candidates for the profession would be materially diminished; but would that be an unmixed evil? It was becoming well known that there were already too many practitioners of medicine, and that it was impossible for them all to make an adequate livelihood. He quoted from some lately published statistics of the General Medical Council, which showed that while the rate of increase of population in England in late years had been 1·4 per cent. per annum, the increase of registered practitioners during the same time had been at the rate of 2·42 per cent. It was stated that "the net increase of the profession in England during the quinquennium 1881–86 was no less than 826 beyond what was requisite to keep pace with the population." In London especially the plethora was extreme; in 1886 it contained 1943 registered practitioners over and above its due share. But if fully-fledged doctors were as thick as blackberries, the would-be votaries of the art were still more numerous; for the last five years an average of 1921 entering medical students have annually registered their names. The lecturer did not adduce these figures to discourage his hearers, but he thought that they forcibly indicated two things—(1) that if competition had been severe in the past, it was certain to be still more so in the near future; and (2) that they would all have the greater need for steady work, and for making the most of their opportunities from the very start if they were to succeed in the struggle. He enumerated a long list of the qualities which various authorities, including Hippocrates, had laid down as essential to the success of a medical man, and from these they could judge what paragons of excellence they ought to be. It was true that occasionally some individual of imperfect education in his work, who had not demonstrated to his professional colleagues at least many of these characteristics, attained by "push," and with adventitious aid, to the position of a "fashionable physician," and acquired a certain amount of reputation among the uninstructed, who could not detect the fraud. But such instances were rare. Considering, indeed, the gullibility of a large section of the public, as evidenced by its trust in everything which was sufficiently advertised, it was surprising that the humbug and charlatan were not more to the fore. All this might be beneath our notice; but the fact remained that, while many a competent practitioner is struggling to make two ends meet, fees which legitimately should go to him find their way to the pockets of unscrupulous adventurers, who thrive on the public credulity, and to the general detriment. (Although the interests of the profession are supposed to be in the keeping of great councils and corporations, such matters as the showing up of such impostors was generally, it seemed, left to the private efforts and expense of members of the profession.) It was satisfactory and only fair, however, to say that the great organs of public opinion at the present day show a due appreciation of the *rôle* of our profession, and are not sparing in their acknowledgments of what a London morning journal has recently called "the inestimable services rendered to mankind by physicians and surgeons," whom it describes as "that true Legion of Honour, the members of which, officers and men alike, lead noble lives," &c. Such words are some encouragement in our efforts. The "barber-surgeon" is long since extinct, and the hybrid medical tradesman is becoming obsolete. The physician of to-day is no longer a mere "coprogogue," nor is the surgeon only worthy of the name of "Sawbones;" and Voltaire's often-quoted dictum, that a medico was "a man who poured drugs, of which he knew little, into a body of which he knew less," is not quite so true now as it was. "We can look with pride to the enormous and steady improvement in the public health wherever the modern doctor has had his say. We can point to the fact that London—this seething cauldron of human beings—is the healthiest city in the world (in spite of the profusion of doctors!) as a concrete result of the attention paid to the advice of sanitarians." He had heard a place described as so salubrious that no one could die there; when the old people desired to depart this life they had to go into the next parish! "But this is not a common experience. We have indeed a huge continent of unknown facts in the causation, prevention, and treatment of disease yet before us for exploration. The points of attack are obvious, and there are plenty of willing and able hands for the work; but the 'sinews of war,' which are as necessary in this campaign as in any other, may be wanting. It must be admitted that in recent years the State has more and more recognised its obligations to the public weal, and has done much for the science of health; but a great deal is still left to private effort and generosity. We have had to await the initiation by his Royal Highness the Prince of Wales and his 'Damien Committee,' of a much-needed crusade of investigation, against one of the most terrible scourges of mankind, and we have had to leave gaps in our knowledge of an important therapeutic agent, until

Digitized by Google

an enlightened Indian prince comes forward and handsomely defrays the cost of its re-examination. May some of our Croesuses nearer home take a hint from his splendid example." The lecturer desired to enter a plea for a more thorough study of physiology on the part of medical students, who did not always grasp the fact that the subject did not merely consist of tables of constituents, series of functions, divergent theories, &c., to be learnt by heart. If they gave as much time to the things which were shown to them in the lecture-room and laboratory as they did to the names which they labour to commit to memory from their "cram" books, they would not find it dry. "The processes of health and disease are not really different in kind. Physiology and pathology are part and parcel of one science. There is no distinct line of demarcation between them; our knowledge of the latter can be but little advanced except through a knowledge, and by the methods, of the former. It will be to the well-trained physiological mind that the problems of disease will the easier yield." Dr. Abraham then offered some practical suggestions in reference to lectures, note-taking, &c., founded on his own experience. He strongly recommended students to use all their senses, and to satisfy themselves that what they were told was correct. It was a mistake to depend upon books rather than upon practical work. After some further remarks on degrees &c. he expressed his pleasure at seeing in the chair his teacher, the brilliant Professor of Anatomy of the University of Cambridge, and thanked his hearers for the patience with which they had listened to him.

SCHOOL OF PHARMACY.

INTRODUCTORY ADDRESS BY PROFESSOR JOHN MARSHALL.

PROFESSOR MARSHALL was prevented by indisposition, which we trust is of a merely temporary character, from being present to deliver the following address, which was therefore read on his behalf by Professor Attfield. After some introductory remarks on the past history and present position of the school in its various departments, Professor Marshall referred to the action of the Pharmaceutical Society as follows:—"It would ill become me, so much a stranger to your affairs, to appraise the merit of any one of the many personal agencies which have been or which are now engaged in your particular educational field; but I must be allowed to offer my opinion that you have already gathered in a goodly harvest. I speak not alone of the stimulus you may have given by your highest distinctions to original or otherwise valuable and elaborate research; but I would say, as a member of my own profession, and as one of the body politic of this great country, it is no idle boast to proclaim that, of the 14,000 individuals whose names are inscribed on your register, about half—i.e., 7000—have passed either your major or your minor examinations. Now this observation leads me naturally to turn to consider the special function which we are called upon to witness and participate in to-day; I mean the award of honours to those who have just been tested in their respective departments of study, and have distinguished themselves by special merit as to their scientific knowledge or their technical skill. I need hardly say that I desire to offer the successful candidates my sincere congratulations, to which I am sure I may add those of the Council, the professors, and the lecturers, on having earned these hard-won distinctions. I may remind them that the receipt of such honours assuredly involves future responsibilities not to be lightly set aside or carelessly neglected. All prize winners are marked men, and their future career does not pass by unobserved. Early rewards received at the hands of an honoured public institution are not only a recompense for past exertions, but should be regarded as pledging their recipients to future efforts for the maintenance of the reputation not only of the individual but of the Society under whose training they have been earned. Nor, rightly considered, should those who have only relatively failed in a competition for a necessarily limited number of prizes be held exempt from the same obligation; for even in regard to them it is impossible to overrate the value of their methodical training and their individual efforts to succeed, nor the general beneficial effect of the race which they have run against others just a little more successful in their scientific and technical contest. ..... It is not for me to intrude my opinions on those debateable questions which involve the commercial interests of the members of your Society—such, for example, as relate to the competition between co-operative trade associations and private establishments; to the necessity which exists in the former case for attaching definite personal responsibility in regard to the purity of drugs, the accuracy of dispensing, and the sale of dangerous poisons; and, again, to the question of the desirability of the State obtaining a source of income from the sale of patented medicines. But I may be allowed to express, as the representative of the General Medical Council, the sympathy of that body towards every endeavour and every practical suggestion which may be made by this Society, with a view of improving the British Pharmacopœia, the responsibility for framing and publishing which is by law vested in that Council. Hence comes a direct and continuous encouragement to your legitimate aims of advancing pharmacology as a science, and of promoting pharmacy as an art. The immediate object of your Society is, as I understand it, to afford the means of a perfect education, general, scientific, and technical, to all your future Members and Associates, so that each and all may attain to a high state of culture, knowledge, and efficiency. Your past history shows that you will not halt in your efforts, but will even yet improve in your methods and in your results. To this end your future students, many of whom, unhappily, are outside the sphere of your influence and guidance, and must often be imperfectly informed as to the fittest course for them to pursue in regard to their education, should seek early in their career some friendly and trustworthy advice. It might not be beyond the scope of the duty of your Society itself to circulate very widely a brief pamphlet, containing advice especially intended for those who are still in the apprenticeship stage. It should be strongly insisted upon that a good preliminary general education is absolutely necessary to all who aspire to be really accomplished pharmacists and to be worthy Members or Associates of your body. It is of the greatest moment, moreover, that the general education of which I have spoken should really be in fact, as in name, *Preliminary;* and therefore the needful examination tests in it should be passed *before* the systematic scientific training is commenced; whilst this, again, should if possible precede the special technical work. It must of course be granted that this last recommendation cannot always be followed; but, if not, at least the scientific habit and scientific mode of thought should be invariably inculcated, even by the practical teacher, as the ever leading and essential guides, by which to interpret and illuminate the simplest technical procedure. In this way the humblest task is elevated; manual dexterity and mental improvement advance together; and every process thus watched, and every result thus accomplished will yield the reward of intellectual satisfaction, and will excite the pardonable emotions of pride and triumph which spring from the dutiful and successful performance of the humblest work. Finally, I would urge in the most positive manner, that not only socially, but professionally, the greatest probability of real success in life will fall to those who have had the most liberal as well as the best scientific and technical education. On the most interesting but perplexing questions relating to *examinations* I am not now prepared to enter at any length. That examinations cannot be abandoned is clear; that there are evils connected with them is obvious; and hence the conclusion is evident that it is the business of examining bodies and examiners to investigate the charges against them and to aim at their improvement. That some examinations may be too feeble and others too severe must also be true; for examining boards will differ as to what is the proper mean. A due admixture of the systematic and the practical form of examinations is absolutely needful, for theoretical questions cannot well be answered *vivâ voce*, and all technical work must be directly tested. The more of the latter the better, and yet not at the expense of the former. Longer time may be required; but the results will be more satisfactory and more fair. Besides this, 'cram' will sink to a minimum, and be even beneficial, for it must take the practical form of doing actual work. I am a strong advocate for the introduction of what are called 'outside' or 'coadjutor' examiners; but this only in co-operation with the institutional teachers, who best know the aims and the extent of the preceding education. Of course, this remark applies specially to bodies, which both teach and examine, and thus it is surely applicable to your own Society. In regard to purely examining bodies, no particular training institution or school should be over-represented on the examining board. In all cases two examiners at least should work together at every part of

Digitized by Google

every subject. As to the subjects which are to be examined in at each time, they are often too many or are too severely represented; either practice is a serious source of overstrain, as well as of illegitimate and unhealthy 'cram.' If the subjects at each examination were fewer, if schedules in certain otherwise enormous subjects were adopted, and if the examinations were more prolonged and practical, 'tutors,' not 'crammers,' would take and keep the field. I cannot close this address without offering your Society my warmest congratulations on the establishment of its research laboratory. It will undoubtedly prove useful, nay, indispensable, to many an advanced student, who, whether trained within your own walls or elsewhere, may aspire to lend his aid in endeavouring to promote real knowledge in ever so simple yet unexplored corner of chemical or pharmaceutical research. But what I would specially refer to is the encouragement which you now offer to the higher and more elaborate and more difficult prosecution of inquiries in what is understood as pure science, undertaken for science's sake. Pharmaceutical chemistry, and, through it, pharmacology, has before it, in the domains of nature, both inorganic and organic, never-ending problems, concerning the constitution and action of remedial substances, which nothing but the highest and most prolonged investigation can pretend to solve. In such inquiries the physiologist must take his share; but, in your own sphere of investigation, they invite you to reap a rich reward, not only in an increased reputation with the outside scientific world, but in the realisation of a corporate pride arising from your own augmented influence, in the increased reliance of the public upon your opinion and guidance, and, I doubt not, in that progressive success which all must desire for you."

ROYAL VETERINARY COLLEGE.

THERE was a large attendance of both old and new students at the opening of the winter sessional course of instruction at this college on Tuesday; the chair was taken by Sir Nigel Kingscote, K.C.B., and Professor Gerald F. Yeo, F.R.S., of King's College, delivered the introductory address. In the course of his remarks he expressed his belief that the mutual distrust between veterinary and human medicine was fast disappearing with the growth of a wider knowledge of each other's methods. It had long been recognised that there was only one physiology of both man and the lower animals, but the mutually supplementary character of human and animal pathology had now become well known, and was daily assuming more importance in each of those branches of medical science. The great progress in pathological knowledge must be attributed to the fact that experimental researches concerning disease in the lower animals have been added to the observations on man. Among the preventive measures of modern times inoculation stood foremost, and it was regrettable that so much scepticism existed as to the efficacy of vaccination. Again, we were receiving every moment more reassuring details concerning the prevention of that uniquely fatal disease, hydrophobia, and no doubt a great future seemed in store for preventive inoculation. But we must not let ourselves be carried too far by the flood of apparent success. In some diseases it fails; in some its efficacy is doubtful; and in some it might be a means of propagating disease.

MEDICAL OFFICERS OF HEALTH.—The annual meeting of the Society of Medical Officers of Health was held at the Guildhall, Worcester, on Saturday, Sept. 28th, Professor W. H. Corfield presiding. At the conference of medical officers which followed, Dr. H. Swete read a paper on the "Actual and Probable Effects of Recent and Prospective Legislation upon Medical Officers of Health." The salaries of such officers ranged from £1000 to £3. He proposed to make the minimum £100 per annum, no private practice to be taken when the salary exceeded £300 a year. Dr. Taylor (Liverpool) thought that no medical officer should be appointed without the highest credentials. He placed no confidence in diplomas. Mr. Willis-Bund, vice-chairman of the Worcestershire County Council, said the question of appointing a medical officer for the county was now under consideration, but there were certain difficulties to overcome first. Dr. Whitelegge, medical officer of health for the West Riding, read a paper on the best means of carrying out the Notification of the Infectious Diseases Act. Numerous speakers took part in the discussion which followed.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ROYAL FREE HOSPITAL.

CASES UNDER THE CARE OF MR. GANT.

ALTHOUGH it is now more than two centuries and a half ago that a loose cartilage was recognised and removed by a Swedish surgeon, Pechlin, it is only since the recognition of the efficacy of antiseptics that a surgeon has undertaken the direct operation for their removal from the knee-joint with anything like confidence. In the following case the body was not completely separated from the synovial membrane, but had a pedicle of sufficient length to enable it to produce symptoms demanding its removal. Formerly the mortality after operation was high; by the direct method Volkmann[1] placed it at 21 per cent., and by the indirect, Larrey's statistics placed it at 12·8 per cent. This did not, however, mean that the others were cured, for in a large percentage when the cartilage was unattached the surgeon had failed to remove it. In the introduction to a case of removal of a loose cartilage from the knee-joint, which we recently published in the Mirror,[2] we mentioned most of the methods of treating the wound after such removal, and some different ways of applying the sutures. Mr. Jacobson,[3] in a paper on the subject of loose cartilage of traumatic origin, has placed the evidence for their occasional derivation from the bone surfaces before the profession. The following notes have been supplied to us by Mr. E. C. Stabb, senior resident medical officer.

CASE 1. *Loose body in the knee-joint; removal; perfect result.*—H. M——, aged forty, was admitted into the Royal Free Hospital, under the care of Mr. Gant, on June 17th, 1889. Ten months previously he had struck his left knee; it was very painful and slightly swollen for a few days. On June 14th, three days before admission, the patient noticed a movable lump on the inner side of that knee. It did not cause him pain or inconvenience in walking, but he had suffered from occasional pains in the joint, especially during east winds, and he was very anxious to have the lump removed. There was no rheumatic history in the family.

On admission there was on the inner side of the left knee-joint a flat, round, firm swelling, about an inch in diameter, freely movable under the skin. On flexing the joint the body slipped outwards under the ligamentum patellæ. The joint was free from effusion, and there was no swelling or redness. The temperature was normal. On June 29th, the patient being anæsthetised, the surface was rendered aseptic, and the body fixed by fingers on the inner side of the joint. A skin incision, an inch and a half long, was made over it; all hæmorrhage being immediately arrested. The capsule of the joint was incised to the same extent. The body slipped partly out, but was found to be attached by a short pedicle about an eighth of an inch in diameter; this was divided; there was no bleeding. Three wire sutures were introduced, not including the capsule. The wound was covered by a strip of oil silk, the surrounding skin dusted with iodoform, and a sal-alembroth dressing applied. The limb was enveloped in cotton wool from the toes to the groin, and over this were placed, in front and behind, strips of Bavarian flannel soaked in plaster-of-Paris, also from the toes to the groin. On July 6th (the eighth day after the operation) the knee was dressed for the first time. The wound was perfectly healed; the stitches were removed. There was no heat or swelling about the joint. The patient had suffered no pain, and his temperature never reached 99°. A dry dressing and the splints were reapplied. On the 12th the splints were discontinued, and the patient was allowed to get up and walk a little, which he did with perfect ease. He was discharged on the 15th, the joint

Digitized by Google

being perfectly free from pain, swelling, or stiffness, and the movements quite free.

The removed body measured three-quarters of an inch in diameter, was flattened and rounded, somewhat elastic, with a slightly nodular surface, and greyish in colour. On microscopic examination it was found to consist of fibro-cartilage. The fibrous portion being small in amount, and the cells very numerous, many of them presenting embryonic characters.

Remarks by Mr. GANT.—The comparative absence of symptoms in this case was unusual, the patient never having experienced sudden locking of the joint in walking, with sickening pain. This may be explained by the somewhat soft consistence of the pedunculated body, and by the fact that it readily slipped into the space behind the ligamentum patellæ. Nevertheless, having regard to the almost inevitable supervention of synovitis, with probable destruction of the joint eventually, it was considered advisable to remove the body from within the capsule, rather than, after the joint had become disorganised from synovitis, to have to resort to operation.

CASE 2. *Epithelioma of leg; amputation; recovery.*—S. G——, aged fifty-nine, married, laundress, was admitted into the Royal Free Hospital on June 17th, 1889, under the care of Mr. Gant. Twenty-six years previously a white spot appeared on the front of her left leg without any apparent cause, and from which she suffered a good deal of pain. The application of ointment was followed by the appearance of a raw surface, which never closed, though on one occasion it scabbed over. The ulcer slowly increased in size, occasionally showing a tendency to heal in parts, but only temporarily. At Christmas, 1888, the patient received a blow on the leg, after which the ulcer became much deeper. For this she was treated with strapping at an infirmary. Before and after this she used to apply zinc ointment to the ulcer. About the beginning of April, 1889, a small hard swelling appeared on a part of the wound, and has gradually increased in size, the pain also being more severe. The patient had worked hard all her life, and had had thirteen children. She had suffered much the last three years from severe attacks of bronchitis, and two years ago had an attack of pleurisy. No family history of tumour could be elicited.

On admission, the left leg was found to be the seat of a long, irregular, ulcerating surface, red and glazed. On the inner part of it over the skin, about midway between the knee and ankle, was a large, irregular elevation, rising in some parts to three-quarters of an inch above the surface, and between three and four inches in diameter. This swelling rose abruptly from the ulcer and was covered with hard nodules, in some parts it was fissured. The skin on the inner side of the elevation was pigmented and infiltrated for a distance of about an inch. There were no enlarged lymphatic glands. The patient complained of severe pain, more or less constant. On June 29th Mr. Gant amputated the limb by anterior and posterior flaps, sawing through the femur just above the condyles, and removing the patella. Wire sutures and drainage-tubes were introduced, the stump was dressed with sal-alembroth dressings, and a posterior plaster-of-Paris splint applied. On July 1st the stump was dressed for the first time and was doing well. It was dressed again on the 5th, when most of the stitches were removed. On the 8th the patient complained of having had a very restless night and a troublesome cough. Temperature 101·6°. Numerous mucous râles were heard all over the chest, and there was dulness at both bases posteriorly. The sputum was profuse, muco-purulent, and nummulated. Up to the 13th the cough and dyspnœa increased in severity. With stimulant expectorants, quinine, and brandy the breathing and cough became easier, and by the 19th the respiratory sounds were nearly normal. The stump steadily improved, and by Aug. 5th the wound was healed and the patient felt strong and well, getting up for the first time a day or two previously.

On microscopic examination of the swelling numerous down growths of the epithelium into the corion were seen, and here and there "bird's-nests."

Remarks by Mr. GANT.—The unusual situation of epithelioma in this case will appear to be due to the fact that the growth had arisen from an old ulcer of the leg, which in itself is not a common mode of origin of epithelioma. The leg was removed above the continuity of the tibia, in order to ensure the less probable return of the growth, and in this connexion it may be observed that the glands were not enlarged. The subsequent course of the case was complicated by a severe attack of bronchitis, but this in no way hindered the primary union of the operation wound, although the patient had attained the age of fifty-nine.

RICHMOND HOSPITAL, DUBLIN.

A CASE OF ABDOMINAL TUMOUR; OPERATION; DEATH; NECROPSY.

(Under the care of Sir WILLIAM STOKES.)

PRIMARY CANCEROUS GROWTH of the stomach is one of the most frequently fatal forms of malignant disease, that viscus being more rarely affected in a secondary manner by extension of growth from without. In the following case the disease appears to have originated in the neighbourhood of the cœliac axis, and to have presented many features rendering the diagnosis uncertain. Operation was performed with the view of giving relief should the nature and attachments of the growth not permit of its removal, and proved of much benefit to the patient, exit being given to a purulent collection and relieving pain. This was not merely a temporary relief, for the patient was free from pain throughout the remainder of his illness, and the operation was more than justified. Another point of interest is the formation of the gastric fistula by sloughing of part of the growth, which had invaded the stomach, some of its contents finding their way through the external wound. For the record of this case we are indebted to Mr. Edgar Du Cane.

J. G——, a farmer aged fifty, was admitted to the Richmond Hospital on Jan. 31st, 1887, under the care of Sir William Stokes (then senior surgeon), suffering from an abdominal tumour. His occupation necessitated a good deal of outdoor work, and before the present illness he had no serious indisposition. He was a moderate drinker, but never smoked. His father died of bronchitis, and his mother after a short illness, with the nature of which he was not acquainted. He had five brothers and four sisters, of whom only two sisters survive, the rest having died in infancy or early childhood. Until Christmas, 1886, he was apparently in perfect health, but at that time he felt slight pains in the abdomen, especially in the left side, and about a week afterwards noticed a tumour, slightly painful and tender on pressure. He saw a medical practitioner in the country, who was of the opinion, after examining him, that he was suffering from an abdominal aneurysm, and advised the patient to apply to a Dublin hospital for treatment. Thus far, beyond the presence of the tumour, no very serious symptoms were present, vomiting and violent pain being entirely absent.

On admission, on Jan. 31st, 1887, the temperature was 98·8°; pulse 85. Urine normal in quantity, pale in colour, and slightly turbid; sp. gr. 1035; no albumen or sugar. The thoracic organs exhibited no trace of disease. He had a pale, anæmic appearance, and complained of wasting, which had rapidly increased for the last three weeks. On examination of the abdomen a hard tumour could be felt by palpation, of an oval form, measuring about five inches by three and a half. It was fairly movable within the abdomen, changing its position according to the posture of the patient; it could be felt at various times in the umbilical, left hypochondriac, and left lumbar regions. The patient preferred to lie on his back, and when in this position the tumour presented itself in the umbilical region, a little above and to the left of the umbilicus. Indistinct pulsation could be felt on palpation, and a peculiar bruit (resembling the bruit de diable of anæmia) was heard on auscultating the tumour. The area over the tumour was dull on percussion. The liver appeared normal in size and position, but percussion over the splenic area yielded a clear resonant sound. Great pain was now complained of in the region of the tumour; frequent vomiting set in; the ejecta contained no blood. The diagnosis was narrowed down to a choice between floating spleen or kidney, and gastric or omental cancer. If there had been a kidney movable to such a degree as this tumour, it would have given rise to severe and constant pain of a sickening character, accompanied by hæmaturia. The absence of splenic dulness, coupled with the bruit, seemed to indicate a floating spleen, yet the tumour had not the characteristic shape of that viscus, and did not present a notched border. The pulsation was not of that expansile nature characteristic of aneurysm, and pressure symptoms were absent. It was therefore thought that the tumour

Digitized by Google

might be gastric or omental, but no definite diagnosis was arrived at. The condition of the patient was rapidly getting worse, and he earnestly desired that some surgical procedure should be adopted. After consultation with his colleagues, Sir Wm. Stokes decided to make an exploratory incision, and to remove the tumour if possible.

On Feb. 14th, 1887, Sir William Stokes performed laparotomy with full antiseptic precautions, and found the tumour to be a malignant growth attacking the stomach and omentum, apparently springing from the posterior wall of the abdomen and involving the sheath of the aorta, which sent a large vessel into it. The spleen was pushed far up under the diaphragm, thus accounting for the absence of splenic dulness. While examining the growth there was a discharge of pus from an abscess on its under surface. The extensive attachments of the tumour rendered it impossible to make any further attempt at removal. A drainage-tube was inserted into the abscess and the free end brought out of the external wound, which was then closed and dressed antiseptically. The patient recovered rapidly from the shock of the operation. Evening temperature, 99·4°.

Feb. 15th.—Patient slept well after a hypodermic injection of morphia, and passed a good night free from pain. Ordered milk diet. Temperature: morning, 100°; evening, 101°. Pulse: morning, 90; evening, 108.

16th.—Wound dressed and looking well; pus coming from drainage-tube. Patient feels very well. Hypodermic injection of morphia given night and morning. Temperature: morning, 99°; evening, 100·4°. Pulse: morning, 94; evening, 110.

17th.—The patient ordered milk, beef-tea, brandy, and chicken broth. Wound uniting; pus still coming through drainage-tube. Perfect freedom from pain. Hypodermic injections discontinued.

19th.—Patient takes food well. Wound united except at the upper end, through which pus comes in fair quantity. Several sloughs removed.

21st.—Patient taking plenty of nourishment; free from pain. Large slough removed, and a great quantity of pus.

Up to Feb. 26th he continued much the same, but on that date, while dressing the wound, fluid containing flakes of curdled milk and pieces of egg was observed to flow through the upper end of the wound, and from its chemical characters it was recognised as gastric juice.

28th.—Great flow of gastric juice through the fistula. Any fluid which the patient takes appears on the dressings, which have to be frequently changed. Injections of beef-juice per rectum four times a day.

March 4th.—Case going on as before. Great secretion of gastric juice. On swallowing some milk it immediately gushed through the fistula. The patient, though free from pain, was evidently sinking, and died on the 6th.

At the post-mortem examination, general peritonitis was present, the intestines being adherent to each other and to the abdominal parietes. Adhesions were formed all round the external wound, uniting it to the stomach, and completely shutting it off from the abdominal cavity. A cancerous growth involving the omentum and anterior surface of the stomach attached to the sheath of the great vessels was found. A probe passed easily through the œsophagus into the stomach, and out of the fistulous opening. The liver was marked by a few tubercles of secondary cancerous deposits. The other abdominal organs were healthy. Dr. McKee, after microscopical examination, confirmed the diagnosis of cancer. Mr. Du Cane exhibited the specimen of this case before the Carmichael College Medical Science Association.

Reviews and Notices of Books.

The Physiology of the Domestic Animals. A Text-book for Veterinary and Medical Students and Practitioners. By ROBERT MEADE SMITH, A.M., M.D., Professor of Comparative Physiology in the University of Pennsylvania. With over 400 Illustrations. Philadelphia and London: F. A. Davis. 1889.

THIS is a handsomely got up and much needed work. Veterinary students in this country have absolutely no English work from which they can acquire a good knowledge of the physiology of the animals whose diseases they are called upon to treat. They have to learn their physiology from some of the small text-books on human physiology which contain many facts that are of little service to them in practice, and omit much with which they ought to be familiar. To take a single instance: if the veterinary student reads any recent work on the physiology of digestion in man, he will find many pages devoted to that process as it affects a mixed diet composed of cooked meat and vegetables, but the composition and the digestion of raw vegetable food is entirely passed over, nor is there any detailed account of rumination—points that are of essential importance in the economy of the animals with which he has principally to deal. No doubt a large proportion of human physiology as now accepted rests upon experiments and observations made upon animals; but it is taught with the modifications that experience has shown occur in his organs and under the conditions under which he lives, and not under those of the domestic animals. The foreign student has great advantages in this respect, and in the excellent physiological treatises of Colin and Thanhoffer can learn from masters of the subject both the mode in which physiological investigations should be undertaken and the reliable results that have up to the present time been obtained.

The work before us fills the hiatus of which complaint has so often been made, and gives in the compass of less than a thousand pages a very full and complete account of the functions of the body in both carnivora and herbivora. The first part is devoted to the consideration of cells, cell life, the physical properties of cells and of the tissues they form, and the chemistry of cells and the chemical processes that take place in their interior. The early chapters of the second part are occupied with the consideration of the processes of digestion, absorption, circulation, respiration, secretion, nutrition, and animal heat, and then with the physiology of the nervo-muscular apparatus. The third part is taken up with the reproductive functions. The author has judiciously made the nutritive functions the strong point of the work, and has devoted especial attention to the subject of foods and digestion, which occupy nearly 300 pages. Here there is much that the medical student might read with interest and advantage. Speaking of the food of horses, cattle, and other animals, it is stated that "a horse will eat 262 different kinds of plants, and has been seen to reject 212; the ox will eat 275 and refuse 218, the sheep will eat 387 and refuse 141. The hare will eat 449 and refuse 125; and the pig, which is omnivorous, and yet which can be sustained by vegetable food, has been found to devour 172 different kinds of vegetable matter and reject 171." In regard to the quantity of food consumed, it appears that experience has proved that solipeds should receive daily 2 per cent. of their body weight in solids, and ruminants 2½ per cent. of their weight. At the same time the student is taught that the food should be adjusted with special reference to the demands which are made upon the animal economy, whether for work, fat, or milk production. Good hay is taken as a type of a food for the larger herbivora, which shows a nutritive proportion of one part of nitrogenous matter to 4·8 parts of non-nitrogenous constituents, cellulose being disregarded; and although this, which may be regarded as the normal proportion, can be under circumstances changed to 1 : 8, or contracted to 1 : 4, the digestibility, and therefore the nutritive value, of the fodder is interfered with if these limits be passed. In the case of hay, again, the amount of fatty constituents is to the nitrogenous matters as 1 : 3·7. If this proportion be diminished to 1 : 2·2, the horse will still be able to accomplish its normal quantity of work; but if reduced below this for the horse, or below 1 : 3 for the ox, the full nutritive value of the food will not be obtained. From a consideration of such precepts as these, the medical practitioner might learn many things that are now neglected.

In looking through the other sections of the work, it

Digitized by Google

appears to us that a just proportion of space is assigned to each in view of their relative importance to the practitioner. Thus, whilst the subject of reproduction is dismissed in a few pages, a chapter of considerable length is devoted to locomotion, and especially to the gaits of the horse. The work is excellently illustrated throughout; and though most of the woodcuts are from well-known sources, a good selection has been made. In view, however, of the importance of the subject, a still better cut of the changes in the teeth from year to year in the horse and ox might have been made. The volume will prove very acceptable to all those who are interested in the rearing and maintenance of horses and cattle, and will serve a good purpose in spreading useful knowledge amongst the laity as well as amongst professional men.

OUR LIBRARY TABLE.

An Introduction to Pathology and Morbid Anatomy. By T. HENRY GREEN, M.D. Seventh Edition, Revised and Enlarged by STANLEY BOYD, M.B., B.S. Lond. London: H. Renshaw. 1889.—Since the first appearance of this favourite text-book, several other competitors have arisen in the same field, and the subject itself has gained considerably more attention at the hands of teachers and examiners. The preparation of the present edition has been undertaken by Mr. Stanley Boyd, who has certainly spared no pains to bring it up to date, and also to considerably extend its scope beyond its former limits. The result is a work which will, as in the past, doubtless prove very attractive to the student. For it has the great merits of being concise and systematic, and of being also furnished with a number of excellent woodcuts. Amongst the numerous additions to the text we notice a highly interesting section upon the etiology of inflammation, in which the "cryptogenetic" or idiopathic, as distinguished from the "phanerogenetic" or simple, traumatic inflammations are shown to be in all probability due to the operation of pyogenic organisms, coupled with impaired tissue-resistance, the work of Mr. Watson Cheyne being largely drawn upon in support of this contention. There is also a chapter on Fever, where the views so ably expounded by Dr. MacAlister are in the main adopted. Among infective granulomata, leprosy, glanders, rhinoscleroma, actinomycosis—all receive fair notice. The subject of inflammation of the blood-vessels is illustrated by engravings from micro-photographs by Dr. Mott. There is also a chapter upon the vegetable parasites—the only part of the book that is insufficiently illustrated,—which is introduced by an excellent discussion of the process of fermentation. In fact, the student will find, as heretofore, that "Green's Pathology" is a trustworthy and useful guide; and when he has mastered its contents he will be possessed of a considerable amount of knowledge which will materially aid in his conceptions of the nature of disease.

Transactions of the American Association of Obstetricians and Gynæcologists. Vol. I. for the year 1888.—This volume is almost entirely surgical, the subjects of abdominal surgery occupying the lion's share, while operations on the perineum concern three papers. A discussion on extra-uterine gestation occupies the last nine chapters. There are two interesting papers on fibroid tumours of the abdominal wall by Drs. Ill and Reed, the former containing a tabular summary of nineteen cases; and one on heart failure in the puerperium by Dr. Lothrop. As regards the perineal papers, there seems at present to be a fashion of fancy anatomy connected with these regions. Photographs of dissections of normal parts stand side by side with diagrams of the supposed condition after injury, on which are based deductions as to the functions of the various constituents of the perineum, and on these, again, descriptions of "new" operations. In our opinion, this is merely building inverted pyramids, an eminently unsatisfactory style of architecture. The base of all such attempts must be careful dissection of the parts as altered by injury in various cases. As regards the chapters on extra-uterine pregnancy, we would remind our readers that the position is the following:—Mr. Lawson Tait has enunciated theories which are highly novel and highly interesting. Their acceptance or rejection must depend on careful observations made in the future by men capable of trustworthy and unbiased judgment. For A or B to say that he is in thorough accord with Mr. Tait does not advance knowledge, for observations directed specially towards the confirmation or rejection of Mr. Tait's theories cannot be possibly forthcoming for some time to come. For A or B to say that they fully expect to find Mr. Tait's theories correct in the future is not illogical. But what good does it do?

An Elementary Text-book of Chemistry. By WILLIAM G. MIXTER, Professor of Chemistry to the Sheffield Scientific School of Yale University. Second and revised Edition. London: Macmillan and Co. 1889.—It must be presumed that the appearance of a second edition proves that a book was wanted, and in regard to the present text-book it may be said with truth that there is real merit, and even some originality, to recommend it. Some sections—that on Crystallography, for example—are excellent, and there are many well-described and well-illustrated lecture experiments. But there are grave faults to balance these advantages. The periodic classification which has been adopted is, in our opinion, most inconvenient for practical study. Why, except for ideal uniformity, should manganese be described before the alkali metals? or copper, silver, and gold before oxygen? Nitrogen, including, of course, the atmosphere, nitric acid, and ammonia, comes in about the middle of the book; and iron, divorced from manganese, near the end. The arrangement does not elucidate the periodic law, and it must be pronounced confusing and therefore bad. It was, moreover, a mistake to include so many scarce and practically unimportant elements in so very slight a manual; it was clearly caused by a slavish devotion to the great generalisation of Newlands (whose name is omitted) and Mendeljeff. How can it concern a beginner in chemistry to know that ytterbium hydroxide absorbs carbon dioxide from the air?

A Junior Course of Practical Zoology. By A. MILNES MARSHALL, Professor in the Victoria University, and C. HERBERT HURST, Assistant Lecturer on Zoology in Owens College. Pp. 440. London: Smith, Elder, and Co. 1887.—This work, notice of which we regret has been delayed, is written by two accomplished zoologists, both of whom have had large experience in teaching. It is of a thoroughly practical nature, and it is intended by the authors that a specimen of each of the animals mentioned should be obtained by the student, and the several points to which attention is directed in the text should be carefully examined. In this way they hope that a sound knowledge may be acquired of the structure of animals representing the principal types of the animal kingdom. The types given are the amœba, paramecium, opalina, and vorticella for the protozoa; the hydra, the liverfluke of the sheep, the leech, the earthworm, the fresh-water mussel, the edible snail, the crayfish, the cockroach, the lancelet, the dogfish, the rabbit, and the fowl. Why have the authors entirely omitted the amphibia and reptilia? The frog, the coluber, and a lizard are all easily obtained. The description of the several organs, with the mode of exposing them, is very clearly given, though necessarily brief. We fail to see the advantage of the indents or setting back of the paragraphs, which gives the book rather the air of a catalogue. The woodcuts, which are forty-eight in number, are remarkably clearly and

Digitized by Google

accurately drawn, and the reference lines and letters, which are of very exceptional occurrence in woodcuts, are easily followed. In each case directions are given as to the mode in which the animal should be dissected. The book is well adapted for what the Germans name self-study, but will prove still more serviceable if the student have access to a good museum containing well-made dissections by a practised hand, which would show him what can be accomplished by patience and care.

Surgical Bacteriology. By NICHOLAS SENN, M.D., Ph.D. Professor of Principles of Surgery and Surgical Pathology, Rush Medical College, Chicago, Illinois. Edinburgh: Young J. Pentland. 1889.—Bacteriology has now an extensive literature of its own, and quite an army of scientific investigators have devoted themselves to this field of research. The fruits of their labour have had a very conspicuous influence on current views of pathology and treatment, and it is therefore of great moment that all physicians and surgeons should be kept to some extent *au courant* with the results of bacteriological discoveries. Unfortunately for many of us, most of the researches are carried on abroad, and the accounts of them are published only in German or French, and are inaccessible to many readers. Dr. Senn has, therefore, attempted a most worthy task in extracting from numerous French and German publications brief digests of the bacteriological writings of the most skilled observers in this department of surgery. The work is very convenient for reference, as the original authors for the most part speak for themselves, and the task of Dr. Senn has been chiefly limited to collating the best work and to making condensed abstracts. Where the results of different observers are opposed, the uncertainty is left, and no attempt is made to close discussions on points which still require further light. We believe the book will be welcome to many of our readers, and all who have not made themselves familiar with this department of pathology ought to avail themselves of Dr. Senn's help.

Analytical Records.

THE ST. BEDE DISINFECTANT.

(THE ST. BEDE CHEMICAL COMPANY, LD., NEWCASTLE-ON-TYNE.)

THIS new disinfectant is sent out in small blocks; and the chief constituents, apart from small quantities of colouring and scenting compounds, seem to be sulphate of sodium, perchloride of mercury, and a little sulphuric acid. The intention is evident: the antiseptic power of corrosive sublimate is well known, and here it is associated with a large excess of sulphate of sodium to make a solution nauseous and violently aperient in case of its accidental ingestion; and with indigo, eucalyptus, and thymol to give it colour and smell. There is ingenuity in the idea, but we fear that so corrosive a mixture will hardly be suitable for general use. Moreover, the value of corrosive sublimate as a deodoriser is not great, and yet deodorisation is one of the most important duties expected from a disinfectant.

FRAME FOOD JELLY.

(THE FRAME FOOD COMPANY, LD., LOMBARD-ROAD, BATTERSEA.)

A fruit-jelly made with "Frame food." It is palatable and highly nutritious.

QUIBELL'S INFALLIBLE DISINFECTANTS—LIQUID, POWDER, AND SOAP.

(QUIBELL BROS., NEWARK, ENGLAND.)

The liquid is brown, syrupy, and concentrated. In odour it suggests cresol and pine oil. With water it gives a white emulsion, which, on addition of soda, clears with separation of some tar oil. Bromine gives a non-crystalline precipitate. In the powder and the soap the same active agents are easily detected. We believe that the preparations, which seem closely akin to some others already extensively used, are valuable as containing some of the most efficient of modern antiseptics.

PERINET ET FILS CHAMPAGNE, RHEIMS, EXTRA SEC, 1884.

(JOHN BARNETT & SON, 21, MINCING-LANE.)

Genuine and very dry champagne, of good flavour. Our analysis gave alcohol by weight 9·85 per cent., equal to 21 5 per cent. proof spirit; extract, dried at 212° F., 2·95 per cent., and ash 0·12 per cent. The wine is well suited for those to whom sugar is deleterious.

DIABETIC SCOTCH WHISKY.

(GEO. BACK & CO., 14, DEVONSHIRE-STREET, E.)

This whisky is almost absolutely free from extractive matter. It yielded to our analysis only 0·0275 per cent. of solid extract and 0·005 of ash. The alcohol amounted to 44·65 per cent. by weight, equal to 91·60 of proof spirit. It has scarcely any colour, and certainly seems to deserve its name.

MARKS' VIENNA FOOD FOR INFANTS AND INVALIDS.

(MARKS & CO., PENTON-STREET, LONDON, N.)

A cooked farinaceous food, as is proved by the microscope as well as by the dextrin reaction. We found wheat starch cells altered by heat, and no adulteration of any kind.

HEINEMANN'S WHEAT COFFEE. MADE ENTIRELY FROM THE FINEST WHEAT MALT.

(F. W. ALSOP, 33, VIRGINIA-STREET, GLASGOW.)

This is a curious, and, we think a valuable preparation. In appearance and odour it resembles coffee, or rather coffee with chicory. Infused as directed it gave an agreeable and nutritious beverage by no means unlike coffee, in which starch and dextrin were readily detected. Such a beverage possesses genuine food value, and will be acceptable to many to whom coffee is too stimulating.

CONCENTRATED WHITE BREAD.

(E. MOGG, ST. MARY-STREET, BRIDGWATER.)

Mr. Mogg evidently prepares excellent bread; but in what respect it claims special notice or why it is described as "concentrated" we do not understand.

NEAVE'S FARINACEOUS FOOD.

(J. R. NEAVE & CO., FORDINGBRIDGE.)

A pure cereal food preparation. The microscope shows the presence of wheat and oat flour, but no sign of any adulteration. It is properly described by its title.

CALLARD'S DIABETIC FOODS.

(S. CALLARD, 146, NEW BOND-STREET.)

No less than ten varieties of Callard's diabetic foods have been submitted to us, and after careful examination we are able to report that all are excellent. For the first five—namely, gluten bread, rolls, rusks, cracknels, and gluten and almond biscuits—it is claimed that they contain no sugar and only a trifling percentage of starch. The remaining five are described as cocoa-nut and almond biscuits, sponge cakes, and Madeira and almond cakes, very slightly sweetened with saccharin. These last are asserted to be absolutely free from starch and sugar. In regard to the samples submitted to us, these statements are entirely true. No sugar or starch was found in the last five, while in the first five there was no sugar but a little starch. Saccharin was present in the last two samples, but in very small and perfectly harmless quantities. In texture and flavour all the samples were admirable, and several would be eaten with pleasure even by persons who were not under diabetic restraints.

UNIVERSITY OF ST. ANDREWS.—A sum of £2000 has, it is understood, been presented to the University of St. Andrews for the purpose of erecting buildings and equipping a chemical laboratory in connexion with the chemical chair in the United College of St. Andrews.

THE LANCET.

LONDON: SATURDAY, OCTOBER 5, 1889.

IT would be easy to disparage the system of introductory lectures in the initiation of the winter's work of the medical schools, but the discontinuance of it would involve the loss of a great opportunity for impressing students and saying a word to the public on the public bearings of medical education. The significance of these bearings is plain enough, and was well brought out in the address of a layman, Sir ALBERT ROLLIT, on Tuesday. He discussed the grievance of the want of a teaching university in London, and a system of higher education which should involve something like a graduated degree system, and declared with a candour creditable to him as a London University graduate, that unless that university quickly rose to the occasion, it would be supplemented by another body. Low medical education is more and more at a discount, in spite of the strange statement in *The Times* that in poorer districts what is chiefly wanted is attendance on midwifery and the administration of purgatives! This is, indeed, a short compendium of medical art, but scarcely expresses the demands of the classes who suffer most and die most from disease, in which fevers, tuberculosis, rickets, bad habits, and bad hygiene have their chief harvest of victims. It may be confidently stated that the only things which will serve men either in poor districts or in richer ones are sound knowledge, kind dispositions, and professional aptitude. This was the burden of most of the addresses, which give no sanction to the idea of cheap education and easy examinations, and which vie with each other in enforcing the necessity for wider general culture, broader acquaintance with allied sciences, and larger professional experience. We cannot with much detail discuss the individual addresses, which covered a large range of subjects, some being strictly educational in their nature and object, others, such as Mr. GODLEE'S, dealing with the history of the profession or one of its branches. Mr. BLAND SUTTON sounded a high note on the importance of accurate observations in anatomy and pathology, not confined to the human species, and gave some very curious instances, what he called intellectual blindness, which will be read with interest. Dr. MAGUIRE traced the history of protective inoculations from that great beginning of JENNER to the last refinements of PASTEUR. At the Veterinary College Professor GERALD YEO ably discussed the same subject, and enforced the advantage of co-operation between human and veterinary practitioners. He made one startling statement, that students in the Veterinary College are better prepared and "show a much more accurate knowledge of the subjects they have to prepare for examination than the ordinary candidates of other qualifying bodies." We leave the teachers and students of human medicine to answer that charge.

The promoters of the "Practical Element in medical education" have no reason to be dissatisfied with the way in which that subject has been treated, notably in the two Addresses which stand out pre-eminently as model Introductory Addresses—viz., that of Professor GAIRDNER at the Yorkshire College, Leeds, and that of Dr. CLIFFORD ALLBUTT at his old school of St. George's. It is much that the arguments for more attention to useful knowledge and the cultivation of practical aptitudes in medical education have been seriously entertained by such teachers, even if, in the end, they have to express dissent and disapproval of particular methods for securing this great result. The mere discussion of such subjects by such speakers in an Introductory Lecture, and as it were, before the public, is a decided gain. No one should know Mr. WHEELHOUSE'S views better than Dr. CLIFFORD ALLBUTT; but we cannot help thinking that he has unintentionally misrepresented him in saying that he is in favour of a reversion to the old practice of a five-years' apprenticeship to a general practitioner. Mr. WHEELHOUSE may have in some recess of his mind an affection for that old institution, as many practitioners have who had the privilege of having men of character for their masters; but we know of no recent deliverance, either by that gentleman or any other responsible person in favour of so impracticable and antiquated an idea. We may leave Mr. WHEELHOUSE, however, to defend himself on this point. He and Dr. CLIFFORD ALLBUTT are not very likely to come to serious blows: the more so as, fortunately for the cause of this "practical element" point in medical education, Dr. ALLBUTT has conceded the essence of what its promoters have urged—that at some stage of medical education there is a place for a student learning the art of practice; what he calls, with perhaps less than his usual force and felicity of language, the "domestic side" of medical work. After the faculties have been trained and strengthened in the main branches of medical education "one year's apprenticeship would do the work of five in an earlier age, and an obligation upon young men thus to apprentice themselves before the completion of their studies would have my approbation and support." This is a large admission, larger even than some of us may think necessary, but it is sufficient to show that in the opinion of so capable a judge there is something which is not taught at present either by hospital practice or any other part of the necessary curriculum of a medical student. The rest of Dr. CLIFFORD ALLBUTT'S address would tempt us to write at greater length; but we must defer further remark at present than the expression of our general acceptance of his view of the virtues and defects of the ordinary medical practitioner and his arguments for raising the general culture of the profession by insistance on university studies and discipline and the cultivation of the philosophic mind. It is almost enough to reconcile young practitioners to the somewhat excessive leisure of early professional life to think that they can use it as Dr. ALLBUTT did in the mastering of GROTE'S "Greece," of GIBBON'S "Rise and Fall," and of MILL'S "Logic," with "some great work of imagination," and so, almost without a university, attain "the university mind." We hope that our brief notice of Dr. ALLBUTT'S address will lead our readers to study every word of it.

It was a happy thought of the Leeds school to secure an address from Dr. GAIRDNER. He might long ago have abandoned himself to the luxury of his own careful

Digitized by Google

studies and consulting practice. But he has preferred to deal deeply and seriously with the very fundamental principles of medical education, and devote a large part of his life to personal teaching. His great text at Leeds was a demand for "thoroughness" in all that students do; not that they should "do many things," but "much." Taking advantage of a humorous newspaper account of the invention of a new automatic machine in the form of a "doctor," which, on the deposit of a penny through a chink, is to supply pills and powders for all "the ills that flesh is heir to," he deprecated routinism, automatism, mechanical prescription in medicine, and vindicated the value of living personal observation and opinion. Men are still fain to be led by other men or by one man. A new heresy in medicine, almost as foolish as any of the old ones, is to swear by the dogmatism of a mystic who lived nearly a century ago—to accept his authority and use his medicine in his doses. Dr. GAIRDNER'S noble defence of freedom mocks all such attempts to bind living medicine with such miserable withes. If men will not be bound by HIPPOCRATES in the nineteenth century, they are not likely to call any other man lord, and of all grave and successful physicians who justify this freedom, none speak with more clear right and note than Dr. GAIRDNER, whose rational treatment has reduced the mortality of whole classes of disease to a minimum, and who is well entitled to say, as he so eloquently did say, "That it is the simple truth that at no time in the world's history have the medical advisers of the sick been so little hampered by traditions as at present; at no time have the methods, the formulas, the remedies of past ages undergone more revolutionary changes, and yet at no time have the living influence, the character, the personal status of the physician and surgeon been more adequately maintained than precisely in the latter end of this nineteenth century." He, too, ran a tilt at Mr. WHEELHOUSE'S views of practical teaching; but he was able to say what we fear many teachers cannot say: that as far as his pupils were concerned, he takes care that they shall not be ignorant of measles and other common diseases. We are too much impressed with Dr. GAIRDNER'S lofty demand for personal work and care in making ourselves *thorough* in teaching and in learning medicine to discuss to-day his criticism of the demand for more practical and technical instruction. We may take other opportunities for that, only remarking here that there is no comparison between the necessity for a practitioner being able to recognise and treat measles or scarlet fever and his being able to operate for hernia. The one duty arises immediately and daily, and failure in it involves immediate disaster and discredit. The other arises rarely, and can, in nine cases out of ten, be devolved without discredit on those who lay themselves out for higher surgery.

THE question of leaving Great Britain for other and better winter climates becomes to a large and increasing class a topic of the first importance, which must be faced during the month of October. This month, although on the average almost the wettest of the twelve, is so frequently mild, that patients are tempted to linger at home until it has run its course; but it is generally recognised that November in this country is not to be encountered with impunity or without grave risk by the class interested in the subject of a winter change of residence. The English winter has the following defects, which render an escape from it desirable to many, and a practical necessity to some. It is a season of short days and sunless skies. Though rarely severe in point of cold as compared with many other lands, it presents great fluctuations as regards temperature and moisture; it is, on the whole, somewhat windy, and especially towards the vernal equinox the winds are parching and depressing. Hence for large classes of sufferers open-air exercise is largely impeded or even entirely hindered, colds and chills are frequently caught, appetite and digestion are apt to become impaired, the general health suffers, and in consequence many diseases are aggravated. It is essential for any accurate conception of medical climatology to recollect that our climate does not act injuriously by any single characteristic, but by a combination of characteristics and by their sum total effect upon the organism as a whole, as well as upon any local affection. Popular language attributes all the defects of the English climate to the damp, whereas our rainfall is small compared with many places in favour as health resorts, and the comparatively low temperature usually prevailing in these islands prevents a very large amount of moisture from being held in suspension in the air. Rainfall, evaporation, relative and absolute humidity, temperature, amount of sunlight, direction, force, and distribution of the prevailing winds—all these factors require careful consideration before any accurate estimate of the effects upon health of any given climate can even be attempted.

As regards the classes who, when means and circumstances permit, may with advantage seek a winter change of climate, we may put the facts generally in this way: all those to whom daily fresh air exercise is indispensable, and who are unable to take such exercise unless under favourable meteorological conditions; all those who from any cause are peculiarly susceptible to changes in temperature and hygrometric condition, and who as a consequence of such changes are prone to catarrhs or deep-seated inflammations; all those in whom a succession of wet or sunless days profoundly depresses the mind and the physical energies. A little reflection will show that the diseases coming under these various categories are—phthisis, bronchitis, rheumatism, marked constitutional delicacy, and delayed convalescence either from a surgical operation, a specific fever, or an acute inflammation.

The advantages of change of climate in phthisis have been known from the earliest times and are universally recognised. The subject is one in connexion with which a large literature is rapidly springing up, and is so extensive that little to the purpose could be said in the course of a leading article. Amidst much controversy on the subject, certain conclusions command at least a very general acquiescence. We are all pretty well agreed that change of climate is the most potent means we have of combating pulmonary tubercle; that it can be recommended with any degree of assurance only when the disease is early and in the main uncomplicated; that the failures are more numerous than the successes, but that the successes are considerable in number, often very striking in character, and sometimes occur in unhoped-for cases; that the sea voyage, the high mountains, and bright sunny, bracing, but not too stimulat-

Digitized by Google

ing or exciting climates, are the various alternatives that present themselves to our choice; and that the selection is still a matter of considerable difficulty and obscurity. One broad and elementary principle may probably be accepted as universally true—that no climate will permanently benefit phthisis unless it permits a large amount of fresh air exercise and acts generally as a tonic to the system.

In some of the other conditions enumerated the choice of a winter climate is a much simpler matter than it is in phthisis. Thus, bronchitis, if there be much cough and secretion, calls for a soothing climate, where warmth and equability prevail —conditions that are found at Madeira, the Canary Islands, the Azores, Nassau in the Bahamas, and many similar resorts. If the secretion be very profuse, such as in cases of bronchorrhœa, a drier climate than the ocean islands will often be desirable, and may be found in many of the sanatoria on the Mediterranean seaboard. Rheumatism, again, has indications that are sufficiently precise. Warmth, dryness, and at least fair equability, are here the desiderata. Egypt, Algeria, and Morocco may be mentioned as fulfilling these conditions. We must remember, in reference to this department of the subject, that if a climate be very warm and dry, it cannot in the nature of things be very equable, since the combination of heat and dryness promotes radiation and necessarily causes a considerable difference between the day and night temperatures and those of sun and shade.

Asthma is a disease for which change of climate is often sought, but such change must always be regarded as an experiment which is to be judged by its results. We are unable to lay down any general laws on the subject, except that the disease is very much influenced by locality, that meteorological features seem to have no constant effect, and that, unlike most respiratory affections, asthma is not aggravated, but often relieved, by the impure air of large cities.

Delayed convalescence and constitutional debility are two conditions for which sea air, whether in the form of the sea voyage or of the marine sanatorium, may be recommended with very considerable confidence, provided in the former case there be neither pyrexia nor great nervous irritability. Strumous children, with weak circulation and a proneness to catarrhs, benefit very decidedly by a sea voyage or prolonged residence at a seaside resort. Mr. TREVES recommends that in such cases places such as Margate should be selected, where large tracts of seaweed lie exposed to the sun at low water, rather than resorts where this feature is absent.

The fashion of wintering abroad must not blind us to the very considerable facilities offered by our own country for the selection of a suitable winter resort. A large number of cases of phthisis will be found to do wonderfully well in the south coast watering-places during the winter. Bath offers attractions to the rheumatic and gouty which are not easily surpassed; Malvern, Tunbridge Wells, Leamington, Llandudno, Southport, and Grange, to mention a few out of many, will be found to yield very good results, as winter residences for properly selected cases.

COLONEL INGLIS, in his report upon the Reformatories and Industrial Schools of Great Britain which has just appeared in the form of a Blue-book, discharges himself from the discussion of any broad questions relating to these institutions on the ground that before his observations could be published the old statutes under which these schools have been managed heretofore would be superseded by fresh legislation. Unhappily the event has not justified his forecast. The two Bills which the Government introduced into the House of Lords dealing respectively with reformatories and industrial schools have both suffered shipwreck, and the questions which they were intended to deal with are still outstanding, having indeed been but little advanced towards solution by the fruitless discussions of the past session. We do not quite share Lord NORTON'S sensitiveness on the score of mingling homeless and destitute children with those who have been charged before a magistrate with some offence; the probably criminal with the accused of crime. The two classes have so much in common that it is probably an over-refinement to attempt to separate them. The case is very different of those juvenile offenders whom a second conviction has qualified for detention in a reformatory. In these instances the presumption of vice is so strong that it is only common prudence to treat them as liable to corrupt other children and to separate them accordingly for education in distinct schools. But between the homeless child whom poverty has thrust into vicious surroundings and the petty offender who is accused for the first time the greatest difference generally is that the one has and the other has not been found out. While, therefore, we do not hold with the excessive multiplication or subdivision of correctional schools, we strongly feel, upon the other hand, that it is a great abuse of the industrial school system that it should be converted into a substitute for the workhouse school, and, if possible, it is even worse that parents should be able to find in the industrial school facilities for getting rid of the burden of their children's support and education. Yet such was the finding of the Royal Commission which recently considered this matter. These are serious faults, which demand a legislative remedy, and one which should be applied without delay. We hope that the pleasing picture which Colonel INGLIS paints this year will not have the effect of blinding the public eye to the defects which his canvas conceals.

As regards the health condition of children in reformatories and industrial schools, the report states that "the health of the schools has been, with a few exceptions, most satisfactory." It is, however, further stated: "The death-rate may seem heavy, but when it is remembered from what a low class the children are drawn, and how many of them come with constitutions enfeebled by hereditary maladies or by poverty and starvation, I think the rate may be said to be satisfactory." While fully admitting the force of Colonel INGLIS'S suggestion as to the effect of the probably enfeebled constitutions of many of the children, we are of opinion that this should be mainly, if not fully, counterbalanced by the effect of the good housing, good clothing, good feeding, and constant care and medical supervision which it may be assumed that these children enjoy. Under these circumstances we find it difficult to agree with Colonel INGLIS that a death-rate which may be broadly said to be nearly double the mean death-rate of all

Digitized by Google

English children of similar ages, living for the most part under far less favourable circumstances, can be accepted as satisfactory. The tables in the report under notice show that the death-rate among the 22,755 average inmates of the Reformatory and Industrial Schools of Great Britain in 1888 was equal to 5·8 per 1000—to 7·6 in the Reformatory and 5·3 in the Industrial Schools. The report before us does not supply sufficient information as to the ages of the children in these schools, to afford the means for testing these rates in a thoroughly satisfactory manner; but if we assume, which we may probably fairly do, that the bulk of the children are aged between ten and twenty years, we find that the death-rate of all children at these ages in England and Wales in 1888 did not exceed 3·4 per 1000. Judged by this standard, therefore, we find that the mortality of children in these schools in 1888 exceeded the average rate by nearly three-quarters, or by 71 per cent. The rate of mortality among the boys detained in these schools was 5·2 per 1000, against the English average of 3·3; and among the girls it was 8·1, the English average being 3·5. The excess of mortality among these school children was, therefore, far greater among the girls than among the boys. Can this degree of excess of mortality be fairly considered as satisfactory? The subject calls for investigation, and in the first place the statistics of a series of years, with the advantage of more definite information as to the ages of the children, would throw much useful light upon the true cause of this excessive mortality.

Annotations.

"Ne quid nimis."

THE PUBLIC HEALTH DURING THE PAST SUMMER.

THE weekly returns issued by the Registrar-General relating to twenty-eight of the largest English towns, having an estimated population of nearly ten millions of persons, afford the means for judging the condition of the public health during the third or summer quarter of this year. The annual death-rate in these twenty-eight towns during the thirteen weeks of last quarter was 18·6 per 1000, which, although exceeding by 1·7 the unprecedentedly low rate in the corresponding period of last year, was 1·4 below the mean rate in these towns in the third quarters of the seven years 1882–88. The death-rate in London last quarter did not exceed 16·5 per 1000, only slightly exceeding the low rate (16·2) in the summer quarter of last year, and was 2·5 below the mean rate in the corresponding periods of the ten years 1879–88. In the twenty-seven provincial towns, however, the mean death-rate last quarter was 20·0 per 1000, thus exceeding by more than a fifth, or 21 per cent., the rate in London. The death-rate in the summer quarter of the year is, especially in towns, almost directly governed by the mortality from infantile diarrhœa, and it is therefore not surprising to find that the increased mortality in our urban population last summer, compared with the summer quarter of 1888, was mainly due to the greater fatality of this summer disease. The annual death-rate from diarrhœa in the twenty-eight towns last quarter was 2·5 per 1000, against 3·5, 3·3, and 1·5 in the corresponding quarters of 1886, 1887, and 1888. This increase of diarrhœa mortality last quarter was due to the hot summer weather in July; the mortality from the disease, however, fell rapidly after the middle of August. In London the diarrhœa rate did not exceed 1·8, against 1·3 in 1888; while in the twenty-seven provincial towns the mean death-rate from the disease averaged 3·0, against 1·7 in 1888. The excess of diarrhœa mortality last quarter, compared with the corresponding period of last year, was relatively much larger in the provincial towns than in London. It appears, moreover, that if we exclude diarrhœa mortality, the death-rate in our largest towns in the past summer did not materially exceed the unprecedentedly low rate in the summer of 1888; and the same is probably true of the mortality in the whole country. It is especially noteworthy that only 2 deaths from small-pox were registered during the quarter in these twenty-eight towns, of which 1 occurred in Leeds and 1 in Sheffield. The mortality last quarter from each of the other zymotic diseases, except whooping-cough, somewhat exceeded, however, that recorded in the summer of 1888. The most noticeable increase, apart from diarrhœa, was in the recorded deaths from diphtheria, which numbered 678, against 394 in the corresponding quarter of last year. On the whole, the public health last quarter, judged by its mortality statistics, although comparing unfavourably with the exceptionally favourable return for the previous summer quarter, was fairly satisfactory, the drawback being a slightly increased mortality from measles, scarlet fever, and enteric fever, and a marked increase of diphtheria mortality.

THE RULE OF COMPULSORY RETIREMENT OF HOSPITAL PHYSICIANS AND SURGEONS.

THE reasonableness of the rule that requires the retirement of physicians and surgeons after a period of twenty or twenty-five years' service is generally admitted. By this time they are generally in such demand outside as to have but scant time for the discharge of hospital duties, which, if they are to be done well, require, above all things, to be done deliberately. So that, for their own sakes and the good of patients, relief from hospital responsibility and work is generally advantageous. Equally reasonable does the rule appear from the point of view of younger men, who have time to spare and who have gifts for hospital service if the opportunity comes in time. And yet the rule has often appeared to work disadvantageously, and to displace men who were not to be easily replaced. It is not surprising therefore that some hospitals have mollified the rule so as to prolong in a practical way the connexion with officers whose term of duty has expired and who may yet, by their experience and reputation, be of the highest use to the institution. We lately found this to be the case at Norwich, where there is a rule of compulsory retirement, we think, after twenty-five years, or on the attainment of the age of sixty-five. This rule has been made since some of the present staff were appointed. It has been qualified by another, which provides "that three beds shall be assigned to every member of the staff who has retired and become consulting officer, to which he may at pleasure admit cases to be under his control and treatment, and for which he will hold himself responsible." We very recently had the pleasure of seeing Mr. Cadge perform a bloodless, successful lithotrity in a little girl aged four. Even he had never done this operation in so young a female. Had the old rule of compulsory retirement been ruthlessly applied to all, he would have been denied an opportunity of doing what he does so well. In this new rule, we believe Norwich only follows the example of the Leeds General Infirmary, which has a rule to this effect: "That any member of the hospital staff shall retire on the completion of twenty years of office, but that on his retirement he shall be promoted to the position of consulting surgeon, and shall be entitled to the use of six beds, provided that in the aggregate not more than a certain number of beds are so

Digitized by Google

occupied by the consulting staff." Under this rule Mr. Teale and Mr. Wheelhouse have retired and yet retain a most important connexion with the institution with which they are so honourably associated. We cannot doubt that this is a good rule, or rather a good qualification of the old rule, and that by adopting it hospitals would secure in their staff the double advantage of what Bacon called "young men and men of age," who have their respective advantages, who are calculated to work well together, to correct each other's faults and stimulate each other's virtues.

CANCEROUS AFFECTIONS OF THE VARIOUS ORGANS IN IRELAND.

WE owe a debt of gratitude to the Registrar-General for Ireland for having taken the lead in supplying statistics of the part or organ affected in fatal cases of cancer. We note with satisfaction that one of the results of the publication of these statistics in the Irish report for 1887 has afforded the means for supplying much more complete statistics for 1888. In the report for 1887 the part or organ affected was not specified in 406, or 19·6 per cent., of the 2067 recorded fatal cases of cancer in Ireland; the report just issued for 1888 shows that in only 67, or 3·3 per cent., of the 2003 deaths from cancer in that year was the part or organ affected by the disease not specified. It is needless to say that the value of these statistics will, apart from their increasing completeness, increase year by year as the records accumulate, and it thus becomes possible to watch the rate of increase or decrease of malignant disease of the various parts or organs. There are, however, one or two facts brought out by the Irish statistics for 1887 and 1888 which deserve notice. In these two years the part or organ affected was recorded concerning 3597 of the 4070 fatal cases of cancer—1578 of males and 2019 of females. If we exclude from the female cases 460 cases affecting the breast and 325 affecting the uterus, the numbers affecting all other parts or organs in the two years are found to be 1578 fatal cases of males and 1228 of females. Of these numbers by far the largest proportion resulted from disease affecting the digestive organs, the pylorus, stomach, liver, intestines, and rectum; the cases so classed in the Irish returns for 1887 and 1888 were 846 of males and 823 of females. The cases attributed to the hand, leg, foot, and to other specified parts not separately classified were 214 of males and 167 of females. There remain to mention the cases affecting the head, face, eye, jaw, tongue, lips, neck, and throat; these numbered 518 of males and 238 of females. Thus while the relative numbers of cases affecting the internal digestive organs were 103 of males to 100 of females, those that we may call the external cases, probably due in great measure to injury from violence, affecting the hand, leg, foot, &c., were relatively 128 of males to 100 of females; and the cases affecting the head, face, eye, jaw, tongue, lips, neck, and throat showed the proportion of 218 of males to 100 of females. If we exclude the cases affecting the head, face, and eye, which may be referred in considerable proportion to injuries, and show less irregularity in the two sexes, we find that the proportion of cases affecting the jaw, tongue, lips, neck, and throat is 333 of males to 100 of females. It would be rash to attempt at present to assign the precise causes for this wide range of difference between the sex proportions of the fatal cases of cancer affecting the various parts or organs of the human body. For this we must wait until a larger basis of facts is available for analysis; and we venture to trust that the Registrars General for England and Scotland will see the advisability of supplying information on this important subject similar to that now furnished in the Reports of the Registrar-General for Ireland. We do not, however, hesitate to affirm that the information is important, as it can hardly fail to throw light upon the cause of the development of the disease, as well as upon the causes of its constantly increasing fatality. Should a larger basis of observations confirm the conclusion, drawn from the Irish figures for 1887 and 1888, that while the sex proportion of fatal cancer affecting the digestive organs is nearly equal, the proportion in cases affecting the jaw, tongue, lips, and throat is 333 among males to 100 among females, it would be strange indeed if it were impossible to discover the true explanation of this remarkable difference. Some deleterious influence specially affecting these parts of the human economy more severely in the male than in the female sex would have to be sought. Without attempting to foreshadow the result of the quest of this deleterious influence in the eventuality alluded to above, it would, for instance, be absolutely necessary to investigate in the most thoroughly scientific manner the effect of tobacco smoking upon the jaw, tongue, lips, and throat, which parts, judged by the figures at present at our command, appear to be more than three times as liable to cancerous disease in the male as in the female.

ALLEGED CASE OF ATROPINE POISONING.

AN inquest was held at Morecambe on the 26th ult. on the body of a boy aged eleven, the son of a Rochdale leather factor, who had been staying at Morecambe during the previous fortnight. Deceased walked to Heysham the previous Sunday (the 22nd) with an elder sister, gathering and eating a few blackberries from the roadside. During the following night he was taken ill, suffering from sickness and diarrhœa. During Monday his mother administered at intervals four or five homœopathic belladonna pilules, which, it was stated, had always suited him very well in previous cases of sickness, and one or two of aconite. Deceased becoming no better, medical advice was sought, but he was then in a comatose state, and died the following morning. The symptoms pointing to poisoning, the deputy coroner ordered a post-mortem examination, which was made by Drs. Clark and Glegg, who expressed an opinion that death was caused by some narcotic or irritant poison, probably atropine or belladonna. Dr. Glegg was strongly of opinion that the pilules administered could not have had any such effect, and it was supposed that deceased must, when out on Sunday, have eaten berries of the deadly nightshade, which are said to grow in the vicinity. After a lengthy investigation the jury returned the following remarkable verdict: "Died from atropine poisoning, and although there was no evidence to show how administered, they believed it to be perfectly accidental." Assuming the above statements, which are taken from the *Liverpool Daily Post*, to be correct, there are several questions which it is to be hoped Drs. Clark and Glegg may be able to answer by a full medical report of the case, poisoning by any of the alkaloids, except strychnia and opium, being comparatively rare, and cases of atropia poisoning being specially interesting. Were any pilules similar to those given to the deceased procured and reserved — because homœopathic pilules are well known to contain, not an infinitesimal, but a very decided quantity of aconite, belladonna, &c., and the quantity contained in four or five pilules would be a very important fact in determining the cause of death? Was the sister asked to indicate the locality and the berries? and what was the exact interval between the eating of these and the occurrence of symptoms? Have the stomach and its contents been preserved, and could not an inspection be made now by some skilled analyst, since it is quite possible to extract and identify the alkaloid which is the active principle of belladonna? Were the symptoms markedly those of atropia and not

Digitized by Google

aconite poisoning? The case furnishes an amount of scientific material which, it is to be wished, may not be lost, but fully utilised for the advancement of toxicology. If the "berries" theory be true, it furnishes another warning to children and their parents.

MEDICAL MISSION WORK IN CHINA AND SYRIA.

WE have often remarked on the importance of medical mission work both in itself and as a factor in the promotion of civilisation and Christianity among heathen nations. Two illustrations are before us as we write: one, the Report of the Medical Missionary Society in China for the year 1888, and the other that of the American Presbyterian Mission in Syria. The former, like the latter, owes its origin and chief inspiration to America, having been founded in 1838 by Dr. Parker of Washington, whose death in January, 1888, constituted an era in the Society's history. At the annual meeting resolutions of a most feeling kind were passed conveying a rare tribute to Dr. Parker's memory as a physician, surgeon, statesman, and philanthropist. Dr. J. G. Kerr succeeds Dr. Parker as President. The Society has a hospital, the Canton Hospital, and several dispensaries. The chief work is done in the hospital, which can accommodate 200 patients. The number of in-patients last year was 1324, of out-patients 6870. The table of surgical operations will give the best idea of the important work done, and the impression that must be made by the officers of the Society. Cholera prevailed and interfered with the work of the hospital, and also with that of the missionaries, who itinerated with medical and religious purposes. Sixty-five cases of stone in the bladder were under treatment in the year, all in men. In twenty-four of these lithotomy was performed, and in thirteen lithotrity. All the lithotrities were successful, most of them being done after Bigelow's method, but five of the cases of lithotomy ended fatally. Catheterisation for retention in men was practised 119 times. One remarkable case of retention of urine in a female from retroversion of the gravid uterus is given. The Bible woman who visited the patient found her somewhat indifferent to her teachings, when she explained her sufferings, and said she had had retention for twenty-five days (?) She went to the hospital on the Bible woman's advice. A female student drew off nineteen pounds of urine with the catheter. She was taken into the hospital. The retroversion was reduced by an inflating or pear-shaped pessary. The catheter had to be used for a month, and the patient recovered. A glimpse like this into the hitherto unexpressed sufferings of millions of human beings, with no law against quackery of the grossest kind, may well quicken the Christian nations in their efforts to enlighten China, and even supply her with some of our superfluity. There is an attempt to teach medicine to a class of eleven young men and three young women. The classes are Chemistry, Theory and Practice of Medicine, Anatomy, and Materia Medica. The latter two subjects are taught by natives. This is not a sufficient curriculum; but in a country with no law to regulate medical practice it is a step in the right direction. Some gunshot injuries were met with in Hainan and dealt with antiseptically. The work of translating medical books has been continued. It is gratifying to learn that half the expenses of the hospital are met by payments of patients and by Chinese subscriptions. The medical work in Syria done by the American physicians of the Medical Department of the Syrian Protestant College, appointed by the Order of St. John in Berlin as the medical attendants of the Johanniter Hospital, is of an equally interesting character, associated as it is with educational and religious work of the very best kind. The hospital in Beirut has received during the past year 491 in-door patients and 8390 patients in the Polyclinique. Our readers know from various communications of Dr. Post in our columns that he brings to his task skill and judgment which, in his native land, would have secured him eminence and wealth. It is work like that of Parker and Post which led the late Lord Beaconsfield to speak of "those sublime men, the American missionaries."

THE "PELLAGRA BACILLUS."

THIS bacterium has been the subject of experiments by Professors Lombroso and Cuboni, representing the Italian, and Drs. Paltauf and Heider, the German, school. Cuboni, it may be remembered, maintains the existence of a bacillus in the maize consumed by pellagra patients, the maize, having previously undergone fermentative alteration. Not only does he profess to have found the bacillus in the maize, but even in the alvine dejections of its consumers. His definition of pellagra is, therefore, this: "a microbian malady, due to a poisoning produced by a pathogenic bacillus." Lombroso's findings, however, were much less confident than those of his compatriot. He, too, found a bacillus in the altered maize, but he failed to detect it in the blood of the pellagra patient, and very rarely found in the intestine. His results have now been confirmed by Paltauf and Heider, who also announce that the bacillus does not produce any toxic principle in its cultures, nor does it, when communicated by inoculation to animals, cause pathological phenomena. The bacillus, in fact, which seems identical with that of the potato is, according to these investigators, "non-pathogenic." The practical upshot of the experiments seems now to be that the maize, owing to a bad system of conservation, undergoes a kind of putrid fermentation, and that from this certain toxic substances are generated, the ingestion of which causes in the consumer a disease, epidemic, but non-contagious, in character. The improved methods of treating the maize, particularly the use of the drying apparatus (*essiccatoio*), have greatly diminished the pellagra following the consumption of the grain. Indeed, the universal introduction of the methods above referred to is confidently expected to extinguish the disease in Upper Italy.

SERIOUS CHARGE AGAINST A MEDICAL MAN.

DR. JOHN EADIE, of West Coker, was recently brought before the magistrates charged with having, on Aug. 22nd last, committed an assault on the wife of George Chick, a shepherd, with intent to ravish her. From the evidence it appears that Dr. Eadie had attended the woman for six months for prolapse and ulceration of the womb, and that from time to time he had introduced pessaries. On the day in question he visited the patient, and, according to her statement, assaulted her. She deposed that she did not scream because "she was so taken by surprise." But this evidence she practically neutralised by saying that she was strong enough successfully to resist Dr. Eadie. The door of the house and the chamber window were open at the time, and a neighbour was sitting outside who could easily have been appealed to. Further proof of the groundlessness of the charge was adduced by the evidence of Amelia White, the neighbour referred to. This witness swore that the woman Chick did not complain to her until about 11 o'clock at night—the assault having, it was alleged, been committed about four in the afternoon. Moreover, Mrs. White averred that Chick had told her to say that she had complained to her about ten minutes after the doctor left. In addition to the want of confirmatory evidence, rebutting testimony was forthcoming The woman was medically examined by Dr. Adams of Martock, who testified to the physical disorder of the uterine system.

Digitized by Google

This evidence was of such a character as to render an assault of the nature alleged in the highest degree improbable. The magistrates who heard the case placed themselves in a somewhat unenviable position, for, at the close of the case for the prosecution, they said that as the evidence then stood they had made up their minds to commit; whereas after Mr. Watts, defendant's legal adviser, had addressed the court and called his witnesses, the chairman said the majority of the magistrates were of opinion that there was not sufficient evidence to commit. Consequently Dr. Eadie was liberated. The defendant's counsel suggested that the woman made the charge whilst suffering from "hysteria and hallucination." The history of this case is unfortunately not singular; charges of like nature have often been preferred against medical men. It is quite clear that neither committal nor conviction should follow unless there is strong corroborative proof, because in such cases the circumstances almost necessarily place the victim in a defenceless position—defenceless except for what he can rely upon from his professional reputation. It is matter of regret that in Dr. Eadie's case the indictment was made under the Acts 24 and 25 Vic., Chap. 100, Sec. 38. If the proceedings had been taken under Sec. 48-52, Dr. Eadie could have been called as a witness for his defence, but as it was, his mouth was closed. We heartily sympathise with Dr. Eadie, and at the same time congratulate him on the issue of the charge made against him. He has suffered what every member of the profession is liable to in the exercise of a noble calling. It is fitting that every recompense should be made him in addition to the public and judicial exculpation which he has received

ACCIDENTS TO WORKMEN.

AMONG the many interesting discussions which have taken place at Paris during the period of the Exhibition, not the least is that on State provision against accidents to workmen. The sentiment generally exhibited by those who took part in the debate was one of admiration for the German system, by which the compensation is paid with absolute certainty to the injured workman. The annuity is paid in the first instance by the employer. If he fails, the corporation of the trade takes the responsibility, and continues the payment. Should the corporation fail, the State itself undertakes the payment. A large class of accidents is due to faults of machinery. It must be hoped that as time goes on these will be more infallibly detected and removed; for many such often no one in particular is to blame. But the prevailing feeling of the Congress was that as society reaped the advantage, it should bear the cost of any injurious result. Mr. Adolphe Smith referred to the case of those working for sweaters, and who sustained accidents without claiming compensation, believing that the sweaters were too poor to pay. In answer to this, it was said that in France the worker, though obtaining his wages through the sweater, would be able to claim wages from the person who employed the sweater. The German scheme is a gigantic one, as may be gathered from the following figures given in *The Times*. By this scheme payments are made through trade corporations:—"Germany had now 62 trade assurance corporations, divided into 366 sections, necessitating 319,453 inspections, and insuring 3,861,560 workers, whose wages were equal to 2,389,349,500 marks. The corporations had paid 5,373,496 marks for 15,970 accidents verified in the year 1887. The minor accidents, treated as illness because the victim was cured in less than thirteen weeks, amounted to 90,031. To the above figures should be added 259,977 railway servants and 6,978,579 agricultural workers. The latter had been compelled to insure by the law of the 5th of May, 1886." The natural objection to such a system is the danger of developing carelessness among men and even among employers; but this, so far, is not supported by facts. The amount paid by employers is said to be less than under a system of insurance. It was generally recognised in the Congress that inspection of factories was best managed in England, especially with regard to the medical examination of children, and all matters relating to hygiene. The great object ought to be to prevent accidents rather than to compensate for them; but meantime compensation is a most just provision. Madame Tkatcheff gave the principles of a proposed law now under consideration by the Russian Government which contemplates compensation in cases of illness due to unwholesomeness of employment.

ENTERIC FEVER AND POLLUTED WATER AT SUTTON-ON-HULL.

ENTERIC FEVER is prevailing at North Ferriby and at Sutton-on-Hull in the Sculcoates rural district. According to Mr. Walton, the medical officer of health, the outbreak at Sutton is due to the contamination of a well used by the residents of a terrace, the pollution being due to obvious soakage of filth. The water has been analysed and found to be impure, but the owner of the well declines to accept the analyst's decision, and hence a sample is to be submitted to a London analyst. This being the case, the question was "adjourned for one week." It is to be hoped that in the meantime the sanitary authority have seen that a water-supply above suspicion is being provided for the inhabitants of the terrace, and also that, in case a favourable chemical report is received as to the recently collected sample, they will remember that the medical officer of health actually saw excremental filth making its way into the well, and that it was the water of several weeks before the date of their meeting, and not that which was recently collected, that must have occasioned the disease, if the water was at fault. In short, the question they have to consider is not so much one of the chemical constituents of a single sample of water collected after the occurrence of enteric fever, but rather whether a water which before the outbreak was obviously fouled runs the chance of being again contaminated.

THE PRINCIPLE ON WHICH MEDICAL MEN SHOULD BE REMUNERATED.

DR. G. WILSON, of Leamington, speaking in Section I., "Sanitary Science and Preventive Medicine," of the Sanitary Congress, travelled over a wide field, from unthrifty marriages and marriages of persons unsound in health or constitution, to the principle of payment of medical men, maintaining that so long as the family medical attendant is paid to attend only on people when ill, and not to conserve the health of the household, there will be a constant drag upon public health progress. Such wide subjects cannot all be discussed in one paper. The subject is a very difficult one. There is much to be said for the public and for individuals paying medical men to *keep* them well. But, as Dr. Wilson said, all our experience of that system is discouraging. The most eminent of our health officers, men worth more "than armies to the public weal," get a remuneration that would not be accepted by a second or third-rate private practitioner, and then often are treated with scant respect. The payment of club doctors, who are paid without reference to illness, is a scandal unworthy of any respectable and intelligent individual of the working-class. Similarly, we could not expect any adequate remuneration from even well-to-do people. It is only the experience of sickness that teaches the value of the healer of the sick. Gratitude is developed, and the office of the physician or

Digitized by Google

surgeon comes to be appreciated. The difficulty of realising obligation to a medical man who simply averts disease is too great to the average practical Englishman. The enjoyment of health is assumed as a natural right—not to be paid for. The very instructions and prescriptions of the physician are lightly esteemed till sickness arises, and the advantage of observing them is experienced, and then the "physician is honoured" by men "for the uses" they "may have of him." Dr. Wilson will not deny that the public spirit and benevolence of medical men make them the great promoters of sound sanitary legislation. Take, for example, their advocacy of vaccination, by which they lose thousands a year, and yet are abused by weak people for doing so with a selfish motive.

THE HOWARD SOCIETY'S REPORT.

IT cannot be said of John Howard that the good he did was "interred with his bones." Apart from the reforms in which he had himself an active share, and which remain as enduring precedents in prison management, the Society named after him continues to labour effectively in the work which he began. Its report for the present year will repay careful perusal. Among other matters it touches on a subject of some importance in referring to the serious and even fatal accidents incurred by some of the inmates of convict prisons in consequence of the dangerous character of their work. Their efforts to effect a change in this particular would appear to be the more needful if, as in a case quoted, coroners' juries are apt to find themselves in some difficulty from the fact that all evidence by gaol officials has to be given in presence of the governor or other superior officers. The natural effect of such restraint may be conjectured. On another page of the report attention is directed to the need which still exists for some system of classification in workhouses and pauper hospitals. The distinction aimed at is one which would separate (1) the vicious or disreputable poor from those who have simply been unfortunate in their worldly circumstances, (2) the sick from fellow inmates whose noisy habits are prejudicial alike to their comfort and their chances of recovery. While the advantage of trained nursing now obtainable in parish infirmaries is felt and acknowledged, it is pointed out, with evident reason, that this in itself can merely palliate the evils occasioned by otherwise defective regulation. It should certainly be possible, in the commodious and well-furnished infirmaries of the present day, to apply such a measure of selection as will guarantee the necessary comfort of patients.

TOBACCO-SMOKING AMONG WOMEN.

TOBACCO-SMOKING, in this country at least, has till recently been regarded as one of the peculiar privileges of the male sex. Of late years, however, the habit has undergone certain important changes as regards the extent of its influence. It has attached adherents by the hundred from among the most youthful of the community, and it has, we might also say, in a great measure changed its sex. Many men, and these as capable, as active, and as worried as their fellows, have always been, and still are, found among the non-smokers; while, on the other hand, a belief seems to be growing that women are largely adopting tobacco in its more æsthetic forms as a feminine perquisite. To its therapeutic charm as an aid to digestion, a soother of worries, and a mild hypnotic, is added its alleged faculty of rendering women more companionable to their husbands or brothers who smoke. On such grounds its wider extension as a social custom has been strongly advocated by some, while others again repudiate it with equal warmth as a veritable poison of domestic womanhood. The question, indeed, is incapable of settlement on purely physiological grounds. It may be freely granted that tobacco does in some degree yield that artificial nerve-rest which is claimed for it; but this will not suffice to silence objection, for its use by the smoker is more than a mere therapeutic method. Like every other luxury, it carries with it something of the slavery of indulgence, and this to an extent not known in the case of the simpler restoratives. While, therefore, we admit that its moderate use is in many instances not only practically harmless, but even beneficial, we cannot allow that its general adoption is at all necessary or likely to prove advantageous. What is true regarding its effect upon men is even more applicable to its influence on women. The companionship of the sexes has, in our opinion, little to gain from the fragrant weed. Concord of the kind suggested is, after all, but a gross bond of union, and the finest common influence we would say is here, as in many other things, not that of "like to like," but of "like in difference."

A PROPOSED MIDLAND UNIVERSITY.

AS a result of the recommendation of the Royal Commission on Higher Education in London that the existing university should so modify itself as to become the representative of the teaching colleges and medical schools in and around the metropolis, or else that a new local university for London should be formed, a meeting is summoned for a very early date in Birmingham of those who are anxious to secure a university for the Midlands on lines similar to those on which the Victoria University has been founded. As any scheme which may be adopted in London to carry into effect the recommendations of the Commissioners will practically put the government of the London University into the hands of London teachers, and provincial interests will thus necessarily take a secondary place, we cannot but feel that there is some reason for the foundation of a Midland University.

INLAYING PORCELAIN IN TEETH.

ONE of the prettiest and most artistic of dental operations for restoring to its pristine beauty a partially decayed tooth is the substitution of its carious portion by a porcelain inlay. We are indebted to Dr. How for having greatly improved the *modus operandi* of this not altogether new course, and bringing it within the region of the practical. Taking, for instance, the somewhat common case of a central incisor requiring filling upon the labial surface close to the gum edge, the cavity is deepened, and with a suitably sized engine burr made perfectly cylindrical, the base of the cavity being left as flat as possible. This being accomplished, a small portion of an artificial tooth, or special sections expressly manufactured for this purpose, which matches the natural one in colour, is mounted by means of shellac on a copper point rotated by the dental engine, and turned down to the required diameter by friction against a corundum file. The section or inlay should then accurately fit the cavity prepared in the natural tooth, and is fastened in position with sandaric varnish or very fluid white stopping. After this is set the surface of the inlay is ground to a proper contour and polished. Should the cavity be oblong two inlays are required, which are fitted separately, and then jointed at the mesial edges, so that the interspace is almost unnoticeable. The applicability of this method is necessarily restricted owing to the varying shape of the cavity; but for many cases of caries of the masticating surface of molars and the buccal surfaces of these and of bicuspids it is useful, though its greatest value is in the case of cavities in conspicuous positions, as in the instance above cited. In such a case it stands in very favourable comparison with any other

Digitized by Google

material the dental surgeon has at his command. Amalgam has a ghastly colour, and, moreover, turns the tooth blue; white stopping has only an ephemeral existence; gutta-percha, subject here to friction, soon wears away; and gold—well, whose eyes have not been offended by seeing an otherwise pretty face marred by a glaring mass of auriferous metal?

CURIOUS INQUEST REPORT.

IN the *Kensington News* of Sept. 21st is a description of an inquest held by Dr. Diplock on the body of a child aged about twelve months, found dead in the Grand Junction Canal. A brick was tied round the neck and the body was quite naked. Death had been recent, as the corpse was not yet cold. A medical witness gave it as his opinion that the cause of death was convulsions, and that the child must have been dead when thrown into the water, and the jury endorsed this view, and returned a verdict accordingly. It may be that the newspaper report before us is inaccurate or incomplete. The fact of a brick being tied round the neck raises at least the presumption of foul play, and certainly the evidence should be very convincing to warrant an alternative theory. The signs of death from convulsions are those of asphyxia, the mode in which death is caused by drowning. We are not in possession of knowledge sufficient to enable us to say positively from post-mortem signs alone that convulsions were the cause of death in any given case. The mere fact of water in any quantity being absent from the stomach or lungs does not prove that death was not due to drowning. This applies with greater force in the case of infants. If death was due to convulsions before the child was thrown into the water, what reason was there to dispose of the body in this way? The wish to be free from paying the funeral expenses would surely be overbalanced by the fear of a charge of murder. We trust that some further explanation will be given in this case; for, as at present reported, it is sadly unsatisfactory.

THE REDUCTION OF HERNIA DURING COUGHING.

IT is an undoubted fact that coughing will produce or bring down a hernia; it is therefore somewhat surprising to hear that coughing may be useful in the reduction of herniæ. M. Vandenabeele, however, has frequently found that herniæ which had resisted attempts at reduction by taxis alone yielded when the patient was directed to cough during the manual efforts to compress the sac. M. Vandenabeele's observations included both inguinal and femoral herniæ, and were not confined to either sex. He believes that during the act of coughing the hernial ring dilates somewhat, and that if well-directed taxis is employed just at the right moment most cases will yield.

THE SALE OF HORSE "BEEF."

HOWEVER desirable it may be in exceptional circumstances of siege or famine to have in our midst available for food a constant supply of horseflesh, there are few persons who will not hail with satisfaction the advent of the recent Bill for regulating the sale of this commodity. Custom has, not without reason, assigned to the flesh of the sheep, or even pig, a higher market value than that of their equine cousin. It is true that the latter contains no really injurious ingredients, and that it is, on the contrary, nutritious, and fairly digestible, but it is also necessarily inferior, as being the tissue of a worked and driven animal, and consequently tough and liable to be loaded with excretory products. It is probable that no small proportion of the cheap so-called beef commonly exposed on the stalls of some salesmen is genuine horseflesh, and that not of the best quality. In our day no healthy and active roadster need fear the pole-axe. His vital powers have a much higher value than his carcase. Consequently we need hardly expect to find this kind of "beef" in prime condition, if indeed it is free from disease. The Act just passed provides that the purchaser shall, at all events, be shown by ample advertisement what was the living shape of the meat he buys. The horse in life will remain a horse in death. A system of regular inspection will guarantee as far as possible the protection afforded by the Act, and the question of a choice of food will thus be put to the public in its plainest terms.

OLIVE OIL TREATMENT FOR GALL-STONES.

DR. KISHKIN has published a paper in the *Meditsinskoe Obozrênië* on the employment of olive oil in large doses in cases of gall-stones, a form of treatment which has been especially recommended by certain American physicians. His observations were made on three patients suffering from gall-stones in Professor Cherinoff's wards in Moscow. In one case only were calculi brought away. These were greenish and somewhat soft. The patient did not improve at all in health after their removal. It was found that similar stones could be obtained by giving olive oil to any person suffering from a scanty secretion of bile; and the stones on examination proved not to be biliary calculi at all, and contained no cholestearin, but consisted of oleic, palmitic, and margaric acids with lime soap. They were evidently produced in the bowel by the olive oil, therefore Dr. Kishkin thinks it is a mistake to attribute to the American method any effect upon biliary calculi.

HUNGARIAN MEDICAL SCHOOLS.

AT Clausenburg the new rector, Professor Klug, in an important address delivered on the occasion of the opening of the session on Sept. 8th, dwelt upon the necessity for more provision for medical teaching for Hungarian medical students. At present there are only two Hungarian Universities—Buda-Pesth and Clausenburg. He mentioned that the proportion of medical schools to the population is only 1 to 7,750,000, a smaller proportion than in most other European countries, the others being Austria (1 to 3,333,333), Germany (1 to 2,250,450), France (1 to 1,541,666), Italy (1 to 1,355,237), and England (1 to 1,095,217). He also calculated the average number of medical students to each university as 670 in Hungary, while in Germany it is only 160. This excessive number of students is very detrimental to practical work, for it is impossible for all of them to get satisfactory clinical experience.

DEATH IN A BATH.

A GENTLEMAN named Chapple was recently found dead in his bath, having been killed, it is believed, by fumes generated by a geyser employed for heating the bath water. It is well that the public should be warned against the danger attending the use of geysers, unless proper means of ventilation be carried out. Whilst the water is being heated an enormous amount of gas is consumed, and the products of combustion must seriously vitiate the atmosphere in a small confined space, such as bath-rooms generally are. Then, too, there is a possibility of the gas escaping unburnt. This, however, would probably be recognised by the smell, and so the danger averted. Every geyser should be fitted with a ventilating pipe. The latter should not be carried out of doors, as the wind may blow back the fumes into the bath-room, but should be conveyed into an adjoining corridor or large room. Further, we recommend the precaution of having the bath-room door open whilst the water is being heated. We have it on

Digitized by Google

authority that ordinary gas jets are preferable to Bunsen's burners. The best apparatus with which we are acquainted is one which is so constructed that if the water-supply fails the gas flame is reduced to a minimum, thus preventing an explosion of steam should the water come on again, and other serious consequences. It is also furnished with a ventilator.

PLAGIARISM.

IT is, we believe, happily a rare thing for a contributor to this or any other medical journal to adopt as his own "original" contribution the writings of another author. Such, however, we regret to say, has been the case with respect to a paper contributed to these columns by F. W. Allwright, M.D., L.R.C.S.I., entitled "The History and Use of Anæsthetics in Midwifery" (1889, vol. i., pp. 983, 1239; vol. ii., p. 589), which, as our contemporary the *Medical News* (Philadelphia) points out, is practically a transcript of certain pages of the valuable article upon that subject contributed to "Hirst's American System of Gynæcology and Obstetrics," vol. i., by Dr. J. C. Reeve. The first volume of the "System" had been in our possession many months, but had not come up for critical notice, as we felt it would be more convenient to review the work as a whole, after the issue of the second volume, which has lately come to hand. Hence our failure to recognise the near identity of the two articles in question. We have communicated with Dr. Allwright, whose reply we subjoin, and who admits that his paper "obtained its foundation from" Dr. Reeve's article, but who does not seem to be aware of the gravity of the charge of plagiarism which has been fully substantiated against him. Nor does he even apologise to us for having used our pages as a medium for the publication of his unacknowledged transcript. We therefore feel bound to notice the matter thus publicly, and to express to our readers and also to Dr. Reeve our regret that the paper in question appeared in our columns. It is obvious that every journal must have complete confidence in its contributors, and that it is practically impossible to guard against such a practice as that referred to, which for the credit of our profession is, we are sure, of unusual occurrence.

"*To the Editors of* THE LANCET.

"SIRS,—In answer to your favour, the article mentioned obtained its foundation from the American 'System of Gynæcology,' but it was not intended to be a copy, nor, I think, is it. An article in 'Buck's Handbook of the Medical Sciences' contains similar facts upon the same subject, as, indeed, must any other history of the same subject. I am very sorry if an objection has been raised to the article appearing in print. I have practised both the method of administering chloroform and also that of ether which is suggested in the article for some time. Perhaps you will offer my apology, and that any offence against Dr. Hirst was unintentional.

"I am, Sirs, yours obediently,

"Brighton, Sept. 29th, 1889." "FRED. W. ALLWRIGHT.

ALCOHOL IN DISGUISE.

THANKS to the folly of mankind, the position of alcohol as a mischief-worker and destroyer of health is at least as eminent as that which belongs to it in virtue of its right and judicious use. We do not need to remind our readers that it has for long wrought, probably more for evil than for good, under other names than those under which we in this country recognise its familiar combinations. Under a variety of titles it exerts its influence as the potent body of the various liqueurs so common on the Continent. These contain, it is true, other ingredients of more or less stimulant character, but they owe their highly intoxicant qualities without doubt to the presence of a large percentage of alcohol. A fact which is not so generally known has, however, been brought to light in some recent returns, which prove that such apparently harmless compounds as "bitters" and "tonics" are also commonly alcoholic in a high degree. Samples examined have revealed the presence of alcohol to an amount varying from 20 to over 40 per cent. Of the legion of adulterations more or less poisonous which have been from time to time introduced into intoxicating beverages our space will not permit us to speak. It is probable that in this case the real stimulant is often the lesser evil. In the presence of such evidence as this, there can be no question that the machinery of official inspection must be made to work with considerably greater nicety than hitherto, if even one desirable end—the purity of known intoxicants—is to be assured. A somewhat simpler task, though till recently but little suspected, also presents itself to them, and to the too-confiding public—this is the detection and exposure of the fraud implied in selling strongly-intoxicant "non-alcoholic bitter tonics."

MEETINGS OF THE MEDICAL SOCIETIES.

THE Royal Medical and Chirurgical Society will hold its first meeting on Tuesday, Oct. 22nd, and the Clinical Society will commence on the following Friday, both being held in the new home of the former Society in Hanover-square. The new large meeting-room there will not be in a sufficient state of completion to be used, but accommodation will be provided in one of the new rooms of the Library. The Pathological Society will meet on Nov. 5th, and the next sitting of the Obstetrical Society will be on the 6th of that month. The Session of the Medical Society of London commences on Oct. 21st; the Lettsomian lectures will be delivered by Mr. Edmund Owen, the Annual Oration by Dr. E. A. Sansom; the subject for the Fothergillian gold medal for March, 1890, being "Peripheral Neuritis," and that for March, 1891, the "Temporary and Permanent Mental Derangements which follow Surgical Procedures." The Ophthalmological Society will meet on Oct. 17th.

EPIDEMIC OF ENTERIC FEVER AT ST. HELENS.

A VERY serious epidemic of enteric fever is prevailing at St. Helens, in Lancashire. Two hundred and fifty cases have within the last three months been notified to the sanitary authority, and it is estimated that about fifty more cases have occurred. In his last fortnightly report, Mr. McNicoll announced that sixty-five fresh cases and six more deaths had occurred, the total mortality having thus reached forty. The infectious hospital is more than full, and nurses are now being engaged to visit and care for groups of sick persons in their own homes. The cause of this large prevalence is by no means clear. By some it is put down to the tub system of excrement disposal, but it hardly seems likely that such a system, even if neglected, can be made accountable for an epidemic which is so widely diffused as the one under consideration. Tub closets, if a cause of nuisance, act as a rule only as a danger to health in the immediate vicinity in which they are situated.

A CORONER'S DECISION.

ON Sept. 20th, a strong healthy young man named John Owens was found dead in bed at Broughton-road, Dalton-in-Furness. On the evening previously to his death he had partaken of a hearty supper of bread and cheese and tea. A brother who slept with him could not say whether he was alive or not when he left him in bed in the morning. Mr. Plant declined to give a certificate of death, but the coroner on making inquiries issued his order for burial, stating that the deceased died from natural causes. Mr. Plant has publicly objected to the coroner exercising his jurisdiction in this
